complication, otherwise it would be much more frequent than it is, though it cannot be described as at all rare. It may be that the co-existence of syphilis is the missing and hitherto overlooked factor, though at present this does not amount to more than a surmise. Mr. Foulerton, who has collated the notes of 499 cases of pyosalpinx bacteriologically examined, finds that the actual presence of the gonococcus was only demonstrated in about 19 per cent., but evidently this proportion cannot be accepted as evidence that the gonococcus was only to blame to that limited In many instances other organisms were extent. found, due to infection from without, or from the adjacent and sympathetically inflamed intestine. It is only fair to assume that in many cases the gonococcus, having lighted up the inflammatory process, dies out, either from want of nourishment or poisoned by its own excretory products. One noteworthy point to which attention was called by Mr. Taylor was the greater amenability of treatment of gonorrheal salpingitis in syphilitic subjects, result which obviously admits of This brings us to the quesinterpretations. tion of the treatment of the originating gonor. rhea, and there seems to be a general consensus of opinion that the disease is not treated in general with the seriousness it deserves. It is not the vulvar or vaginal inflammation which constitutes the direct source of the mischief, but the infection of the cervix of the uterus whereby the inflammatory process gains an entry into the more internal parts. It is not unlikely, as suggested, that treatment directed to the cervix, when found on vaginal inspection to be infected, might stay the further progress of the morbid process and save the tubes from implication. The routine treatment by vaginal irrigations can obviously have no effect on the inflammatory process when once it has gained a footing in the cervix, and nothing short of drastic local measures can possibly be attended by any measure of success-Another point in the treatment which merits more than passing attention is the alleged efficacy of antisyphilitic treatment even in cases where no syphilitic history can be elicited. The administration of mercury associated with the application of either mercury or nitrate of silver to the cervix is claimed to go far in arresting the disease in its initial stage, and these are points which the practitioner ought to bear in mind. Of course, when we are discussing the prevention of a disease the results are open to criticism, because only the results of observation on a very large scale will enable us to affirm an unquestionable beneficial action. Inasmuch, however, as the treatment conforms to one's theoretical notions it is sure to command respect, and we cordially commend to the consideration of our readers the interesting and instructive discussion which followed the papers published elsewhere.

DR. W. SENN, of Chicago, has come forward as a candidate for the Governorship of Illinois, on the Republican

Aotes on Current Topics.

The Bacteriology of Meat Infection.

THE comparative frequency of cases of poisoning by alimentary products, vaguely described as ptomaine poisoning, gives a peculiar interest to the real nature of their causation. The subject as a whole is involved in very great obscurity, partly due to the fact that our knowledge of the intimate processes of albuminous disintegration is notoriously incomplete. Another difficulty arises from the fact that these processes are very fugitive and run through their various phases with great rapidity. It is probable that the deadly chemical substances which are responsible for the grave symptoms that sometimes follow the ingestion of tainted meat are transitional products, here to-day and gone to-morrow, so that they often baffle all attempts to demonstrate their existence. There is reason to believe, moreover, that the somewhat clumsy methods of research at present employed in these investigations are ill-adapted for the detection of such unstable bodies as the incriminated toxins. Considerable interest, therefore, attaches to the researches brought last week before the Pathological Society by Dr. Durham, who has attacked the problem from quite another standpoint. Thanks to the publicity given to Widal's reaction for typhoid fever, most people are by this time familiar with the phenomenon known as "clumping." Briefly stated, clumping is the tendency displayed by certain microorganisms to group themselves when, to the fluid containing them, is added the serum of an animal which has been immunised against these particular microbes. It follows that if the serum of a patient who is suspected to have been affected by a particular microbe, gives this reaction with a culture of the incriminated microbe, we should be justified in inferring that the suspicions were correct. There remains the question whether the symptoms caused by the ingestion of tainted food are due to infection by the living organism or are really symptoms of intoxication by the products which it elaborates The balance of evidence is in favour of their being cases of infection, but we are still only on the threshold of the subject, and much painstaking research is still necessary before the precise significance of these various phenomena will be made clear.

The Surgeon's Wardrobe.

UNDER the stimulating influence of a firm belief in the gospel of antisepsis many modifications in the apparel of the operating surgeon have been suggested, and some of them have actually been carried into practice. It is not so very many years since that the hospital surgeon put on his oldest coat before taking the knife in hand, but that ill-conditioned, greasy, and blood-stained garment has been relegated to the dusthole and its place taken on self-respecting surgeons by a clean linen overall. The apron has not yet become acclimatised in this country, though its use is universal elsewhere. More recently it has been urged that the surgeon ought to have a clean-shaven face in order that the dust from

beards and moustaches should not fall upon and infect the patient. Failing this, he is advised to wear a mask. The latest crank of this kind is the proposal to operate in rubber gloves. What a prospect for the future! Dressed in a shiny pink dust-proof overall, with a mask coloured to fancy, and wearing rubber gloves, the surgeon of the twentieth century will be an object, if not of beauty, at any rate of curiosity. Let us hope in defence to the patient's susceptibilities that when arrayed in full canonicals the surgeon of the future will not come upon the scene until the patient has been mercifully rendered unconscious. Otherwise the element shock will certainly have to answer for an increase in the mortality after operations.

Hospital Reform.

THE burning theme in the rank and file of the medical profession is the abuse of hospitals. So it has been for the last score of years, and so it will continue to be, so far as one can judge, for many a year to come. This being the case it is not a little curious to see the half-hearted way in which medical men handle any movement which has for its end and aim the removal of that particular abuse. Here, for instance, is the Hospital Reform Association, moderate in tone, exact in method, with a comparatively scanty, albeit enthusiastic, following that tells volumes of the apathy of the profession. Well may philanthropists laugh the general practitioner to scorn, and go on swelling the already huge medical charities, and encouraging those who afford to pay fees to contribute to the proceeds of the devastating hospital-monger. Last year it was pointed out at Edinburgh that the medical profession should be fully represented on the management of every medical charity in the United Kingdom. It is all very well to growl and grumble, but something more is needed, for that kind of thing never yet mended an abuse. The subscription to the Hospital Reform Association is five shillings, and the energetic secretary, as everyone knows, is Dr. Garrett Horder, of Cardiff. Every medical man who feels the stress of hospital competition-who that deals with the middle classes does not ?-will do well to join this movement. The mere mustering of medical practitioners, with a common object in view. is a desirable thing. There could hardly be a better inscription for the rallying business than that of " hospital reform."

Wooden Water-pipes.

A RELIC of the good old times—we had almost forgotten our serious mission for the nonce and had written the good old "piping times,"—is now to be seen in some of our London streets. Lying by the side of the highway are numbers of moderately-sized lengths of tree trunks with a good sized hole bored through the centre. These are the water-pipes of our ancestors, but they have been replaced by iron in this progressive age, just as the famous wooden walls of Old England have given way to steel. In the light of the modern knowledge of germs it is interesting to

speculate on what must have been the condition of water conveyed through several miles of decaying logs fastened together end to end. It would have been hard to invent a more perfect plan for fostering and breeding microbes of all sorts and conditions. Yet our forefathers lived through it all, that is to say more or less of them survived, and that at a time when there was only a tithe of the surplus population about which we are all complaining nowadays. What better lodging could the merry microbe wish than the soft dark interstices of a water-logged wooden pipe? Yet the ways of microbes are manifold, and not by any means known to us yet in all their inwardness. Epidemics spread by water delivered through impervious iron pipes have been with us ever since the introduction of these pipes and filters! What old-fashioned wooden pipe could be worse for poisoning water than the average modern filter until we got the Pasteur porcelain filter type.

Intestinal Worms and their Symptomatology.

THE symptoms associated with the presence of parasitic worms in the alimentary canal are curiously inconstant. In some instances the symptoms are merely those which might be expected from the mechanical effects of their presence, but in others they determine constitutional disturbances which may assume a grave form, running on to epileptiform convulsions, and even syncope. It is customary to attribute these symptoms to "the reflexes," but this is merely a refuge for the destitute in the matter of diagnosis. A possible explanation may be found in the toxicity of the excreta of these parasites, as suggested by Mr. G. H. F. Nuttall in an American contemporary. Various observers have placed on record the existence of irritating properties in the tissues of certain varieties of intestinal worms, provocative of sneezing, intense conjunctivitis with chemosis when accidentally brought into contact with the eyelids, and even of cedema of the glottis and aphonia, when inhaled. It must be borne in mind that these parasites are living beings which discharge excreta like other living animals, and it is probable, though it would not at present be safe to speak more affirmatively, that these excreta may, under certain circumstances, either in the diet or the idiosyncrasy of their hosts, provoke constitutional symptoms of a toxic character.

A Nurse's Action for Inadequate Instruction.

A RATHER novel action is being tried at the Bristol County Court, where an aspirant nurse is suing Dr. W. L. Christie for damages on the ground of fraudulent misrepresentation and breach of agreement. Dr. Christie, who is M.D. of New Zealand and F.R.C.S.Eng., is stated to be the proprietor of a private adventure cottage hospital at Bedminster, and to have advertised for young women desirous of being trained as nurses in exchange for a fee ranging from £5 to £10. The scope of the instruction may be inferred from the fact that three months' training was

assumed to fit the probationer for the duties of district nurse. Lectures were to be given daily, side by side with practical instruction at the bedside. The plaintiff gave a lamentable account of the "hospital." which, it seems, is part of a house for which Dr. Christie paid fifteen shillings a week rent. There was no kitchen, and apparently only one ward, a room upstairs containing two beds, a cot, and a cradle. The plaintiff complains that there were no in-patients from January 19th to March 4th, no lecturer, and virtually no tuition at all, so she left. As the case is still sub judice we abstain from the comments which our pen itches to make, but whatever view the jury may take of the merits of the case the circumstances show in a clear and unfavourable light what a fallacious and utterly untrustworthy thing a "training" may be. Even if Dr. Christie had fulfilled his contract to the letter, let us suppose for argument's sake that he had done so, what would be the value of three months' training at such an institution? Really, not enough to enable the aspirant nurse to deal with the simplest case. We defer further observations until the case has progressed to the bitter end.

County Councils and Quacks.

THE Durham County Council has taken a decided step to deal with the rampant quackery prevailing in They have framed a bye-law, the their district. object of which is to deal with the vendors of quack remedies who infest the local towns, and swindle the public by inducing them to purchase their goods. Primarily, this new movement is for the purpose of protecting the local tradesmen, but it will do further good by protecting the public against themselves. If the public were not easily gulled the trade of the quack would soon cease, but a plausible quack can usually beguile an ignorant, unsuspecting, and confiding person into buying worthless and messy concoctions. We trust that the example here set by the Durham County Council will be followed by the other Councils throughout the Kingdom. It is certainly a step in the right direction.

Consultants as "Cutters."

"CUTTERS" is a term of opprobrium applied in the world of pharmacy to those enterprising retailers who seek "small profits and quick returns," but it finds an application even in the medical world. The latest, and possibly the most objectionable, scheme which has thus far been foisted on the profession is that emanating from Birmingham. At the recent annual meeting of the Hospital Saturday Fund of that city it was proposed to engage the services of a physician and a surgeon at a princely salary of £500 yearly, whose privilege it would be to give consultations at half-a-guinea apiece to all and every. The scheme is grotesque on the face of it, and is based on an utter misconception of what constitutes a consultant. A reputation as consultant is not the necessary appurtenance of any medical or surgical degrees or diplomas. It is the outcome of a long period of hard work and gradually extending experience which ultimately place certain

men in a position of superior knowledge and wider experience than is the lot of the average practitioner. When a man has attained that position his work is cut out, and he is not likely to solicit the doubtful honour of giving consultations at a hugely reduced fee. At the salary proposed the managers of the Fund can only hope to secure the services of ambitious young men who are postulating for the position of consultants, a status which they cannot as yet have attained. We can at present only touch on the more obvious absurdities of the scheme as a whole, but when we have an opportunity of considering the practical working details, as we propose to do shortly, the absurdities will become even more apparent.

The London Chamber of Commerce and Secret Commissions.

THE Committee of the London Chamber of Commerce have replied to the protest addressed to them by the Council of the British Medical Association, calling attention to the accusations made against medical men in regard to secret commissions which appeared in the public press some time ago. The reply is most unsatisfactory. The accusations are neither substantiated nor withdrawn. All that the Chamber of Commerce have admitted is that the information upon which their report on secret commissions was based was furnished them in confidence by a "pharmaceutical chemist," and "a jeweller, optician, and silversmith." That is to say, a series of most damaging statements are made against the profession on the testimony of two persons into whose bona fides in the matter the Chamber of Commerce have apparently taken no trouble to inquire. Nevertheless, the reply states that the Chamber of Commerce "believe that the information received by them fully justifies the statement" regarding the secret commissions paid to medical men. Surely, however, it would have been better if this commercial body, before believing anything, had taken the trouble to verify to them. We submit statements made that in the absence of any confirmatory inquiries the accusations to which we allude cannot be regarded as anything else than worthless. Moreover, the Committee of the London Chamber of Commerce must see that they owe it to the medical profession either to withdraw or confirm the charges which they have made. If they cannot produce evidence in support of the latter, then they should have the common fairness to make the amende honorable, and withdraw what they have said.

The Size of the Brain as a Measure of Intellect.

It is generally assumed that there exists a distinct relationship between the size of the brain and intellectual capacity. There are not wanting facts, however, which run counter to this view. One salient example is that of the late French statesman, Gambetta, whose brain only weighed 1,200 grammes. On the other hand, the heaviest brain on record is that of the steamship companies concerned the urgent neces-

a London newspaper boy, whose brain weighed 2,400 grammes, in spite of the fact that he is stated to have been "a bit of an idiot." A brain weighing 2,340 grammes once belonged to a Scandinavian peasant, of whose intellectual status it may be said that "previous to the age of seventy he never showed signs of any extraordinary intelligence, and he has never shown any since." A female Indian dwarf had a brain which weighed no less than 2,200 grammes, being seventy grammes heavier than the brain of Tourgeneff, the celebrated Russian novelist. The average weight of the human brain has been variously put as from 1,500 to 1,650 grammes, and an analysis of the brain-weights of sixty intellectual men works out an average of 1,776 grammes, which is not much superior to the average. Evidently quantity of brain substance is of less importance than quality in respect of the possession of intellectual qualities of a high order. It is less the number of cerebral cells than the way in which they are grouped and connected up, and the facilities for prompt and efficient regeneration. These are conditions and processes which are for the most part beyond the ken of the physiologist, be he never so painstaking.

Tuberculous Persons on Passenger Ships.

A COMMUNICATION in a morning contemporary last week drew attention to an important detail concerning the welfare of passengers on the large steamships carrying the mails to our Colonies and elsewhere. Upon some of the vessels it regularly happens that tuberculous persons are conveyed, generally those suffering from advanced phthisis, and no provision is made for their special isolation. That is to say they are placed in the same cabins with healthy passengers in which combined spaces, of course, especially during rough weather, the ventilation must be of the worst. A specific instance is related in which two cabins containing four berths each were occupied by one or more passengers suffering from advanced phthisis. Clearly in their own interests it would be advisable for the directors of the steamship companies to provide separate accommodation for tuberculous persons; the danger of infection is, perhaps, less on a sea voyage than would be the case under ordinary circumstances owing to the free presence of ozone. But of late so much has been said publicly regarding the infectiveness of tuberculosis that an element of sentiment has now been introduced into the matter, and the public have come to understand that they must avoid exposure to such infection at all hazards. We think that this feeling is the right one to encourage. The more care the greater safety. In the past there can be no question that much of the dissemination of tuberculous affections was directly due to the neglect of precautions against the conveyance of infection; consequently any step designed to prevent healthy persons from coming into contact with tuberculous ones under conditions favourable to the dissemination of the disease, should in these days receive every consideration and attention. We earnestly commend to

sity of complying with the demands of the time in so far as the isolation of tuberculous persons is concerned.

Is the Supply of Oxygen Coming to an End? LORD KELVIN must plainly now be included among those disturbers of the public peace who promulgate unpleasant notions. In a word he has announced as the result of some researches that the supply of oxygen in the world is coming to an end. His conclusions is based upon the following The total amount of combustibles in the world, in the form of gas, peat, and coal, has been estimated at 340 million million tons, and each ton of coal consumes during its combustion three tons of oxygen. Consequently, in view of this ratio, unless some other means can be discovered of obtaining power, long before the world's coal supply has been used as fuel, he holds that all the oxygen will have been used up which gives life to the fire. But in basing some remarks upon these facts an American scientist has "gone one better," to use a common expression. He does not hesitate to state expressly that it will be necessary in the future to resort to artificial air in order to preserve life. He believes that huge artificial air meters will have to be erected whence people will have to adjourn to draw their daily supplies of oxygen. Further that the only possible way of existing at all will be for both men and women to wear air helmets like those used by divers. But so far it will be seen that these pessimists have only considered the needs What about animals? Under the of mankind. shadow of an airless world no animals could exist. and as mankind has to consume animals in order to live, an airless world would be useless to men even if they found means to supply themselves with oxygen. Upon the whole, then, the matter need not be taken seriously—just for the present.

What is the "Strumous" Diathesis?

We are within, approximately, a few months of the dawn of the twentieth century, and yet it seems there is someone desirous of retaining the use of the obsolete terms "strumous" and "strumous diathesis." Sir Dyce Duckworth, in his Harveian Oration last year, expressed himself to the effect that, in many cases neither tubercle bacilli nor caseous matter be detected in the enlarged lymphatic glands of "strumous" individuals; but that the glands represent a good soil wherein tubercle bacilli may lodge and induce caseation should they gain entry, and hence he concluded that "the peculiarity of the lymph system justifies the use of the term 'strumous inflammation, independent of the modern idea of tuberculosis." These being Sir Dyce's opinions, it would be interesting to learn from him his precise explanation of the pathology of the particular inflammation which he describes as "strumous." He claims that it is not tuberculous, or dependent upon the tubercle bacillus. But this is a curious position to take up, for the term "strumous" was introduced especially for the purpose of describing

those forms of disease which we now know to be due to tuberculosis. If Sir Dyce Duckworth's "strumous inflammation" is not caused by the tubercle bacilli, by what is it caused? The question is merely one of pathology, and as modern pathologists have altogether discarded the obsolete term "strumous" for that of "tuberculous," which correctly describes the pathology of those diseases dependent upon tuberculosis, it is clearly a retrograde and antiquated step to endeavour to retain the former term. In a few years the word "strumous" will be almost forgotten; even now we doubt whether medical students of the present generation ever hear their teachers use it, for it has been displaced by "tuberculous," and what is "strumous" is "tuberculous," and what is not "tuberculous" is not "strumous."

Anti-Vaccinationist Martyrdom.

Now that Mr. Balfour's ministry have provided an easy exit to the anti-vaccinationist by way of "conscientious objection," it is not a little amusing to see how some obstinate followers of the cult still insist on posing as martyrs in the police-courts. Too lazy or too stiff-necked to avail themselves of the device that has been contrived for their behoof with such sapient cunning, they fail to enter the necessary formal notice demanded by the Act. Then they are summoned to face the magisterial presence, from which they emerge sadder at the loss of a fine and prouder with the crown of a self-made martyrdom, but we fear hardly wiser men from their experience. Last week one of these obstinute subjects of the realm informed a London magistrate in so many words that he intended to put the law at defiance. He was promptly fined a sovereign and costs, and declared he had no money, and would go to prison for seven days in default, but he was allowed a week further in which to reconsider his decision. With this kind of behaviour one can have little sympathy. After years of clamour the anti-vaccinationists have persuaded not to say coerced—the Legislature of this kingdom to grant them a concession that is condemned by practically the united voice of the medical profession as fraught with danger for the future. Those who choose to go to gaol in spite of this sop to their ignorant faddism cannot be said to deserve a better fate. The man who defied the law before the Balfourian loophole took up a position that we could comprehend; but now-well-we shall have more to say when the next epidemic of small-pox is within the walls.

A Curious Case of Intestinal Obstruction.

At the recent meeting of the German Surgical Congress, Rehn, of Frankfort, reported a curious case of intestinal obstruction. The patient was a servant girl, 25 years of age, in whom he had occasion to resect part of the small intestine. She made a good recovery and returned to her work, but four months later she came complaining of severe abdominal pain and constipation. The symptoms ultimately developed into those of acute intestinal obstruction and abdominal section had again to be

performed. At the operation the obstruction was found to be due to a gauze compress. The mystery, of course, was how the foreign substance had come to be located in the intestine. Rehn thought it highly improbable that the compress had been accidentally left behind at the first operation, and had lain for four months without giving rise to any symptoms; and yet the only other solution to the mystery remaining was that the patient had swallowed the compress. There was, however, no history whatever of this having occurred, and it is very difficult to believe that the patient could have done any such thing. Thus the mystery remains unsolved, the case being one having many points of interest.

Dogs and Hospitals.

WHATEVER hospitals may have done for dogs, the time seems now to have come when dogs will be called upon to do something for hospitals. An experiment is about to be tried at the Royal Free Hospital of holding a medical dog show in aid of the building fund of the London Medical School for Women. Qualified practitioners, members of the teaching staffs of the medical schools and medical students are invited to send their canine friends for exhibition. Again champion dogs will be on exhibition as a special feature of attraction. The day fixed for the show is Saturday. June 3rd, between the hours of half-past one and seven o'clock p.m. All those who desire further information thereupon should communicate with the Honorary Secretaries, 8, Hunter Street, Brunswick Square, W.C.

Alkaptonuria.

ALKAPTONURIA is the term applied to a curious abnormality of the urine which, though apparently very rare, is of considerable interest to the physiclogical chemist. The most salient feature of the urine in these cases is that, although of normal appearance when passed, it promptly acquires a deep brown colour on exposure to air. This coloration is greatly intensified by alkalies, and although no sugar is present the urine reduces Fehling's solution. The first instance of the kind on record dates as far back as 1822, when Dr. Alexander Marcet read an account of a case before the Medical Chirurgical Society, the patient being an infant only eighteen months of age. Since that time some thirty-three cases have been published, including four observed by Dr. Pavy. In a paper read at a recent meeting of Royal Medical and Chirurgical Society, Dr. Garrod called attention to the principal features of this curious and rare affection. We call it affection, but in point of fact its presence does not appear to be incompatible with good health. It is much more frequent in males than in females, in the proportion of twenty-three to eight. nomenon sometimes shows itself early in life, sometimes even from birth, it is sometimes constant, but occasionally intermittent. Although it may present itself in several members of the same family it does not appear to be transmissible from one generation | the Royal College of Surgeons in April last.

to the following. Dr. Garrod's researches point to homogentisinic acid as the one constant abnormal substance present in alkapton urines. This substance in an alkaline medium displays a marked affinity for oxygen, with which it combines to form a dark pigment. It is quite possible that this condition is more frequent than might be supposed from the foregoing figures, but that owing to one's ignorance of its nature that it has escaped recogni-

The Council of the Royal College of Surgeons, England.

From several points of view the election of councillors of the Royal College of Surgeons this year will be remarkable. First of all, there will be only two vacancies open for competition, and each of these will be competed for by the present holders of the appointments. Next, Sir William Mac-Cormac, whose term of office expires this year, by whom the third vacancy would have been created, happens to occupy the Presidential chair, this office being a yearly one, which terminates after the Council election in July. The bye-laws provide that under circumstances of this nature the President shall continue as a member of the Council for a year after the expiration of his ordinary term. Thus, if Sir William MacCormac has the honour again conferred upon him this year of being elected President, he will still find himself a member of the Council for another year in 1900. The retiring members are Mr. Jessop, of Leedsand Dr. Ward Cousins, of Southsea, the Presidentelect of the British Medical Association. It is also worthy of note that no councillor has died, so far, during the collegiate year, which will close on June 30th next. However, apart from these facts, the probability is that the election will prove tame and devoid of any excitement. Only on very rare occasions has it happened that a retiring councillor who seeks re-election has been unsuccessful; consequently under these circumstances it is probable that aspirants for the Council will forego a contest this year, and wait for a more favourable opportunity of securing the suffrages of their constituents.

The Midwives Registration Bill.

This measure, with many others of greater merit, may be regarded as lost for the present year. It was talked out by Sir William Priestly, its leading advocate, but was really killed by Mr. T. P. O'Connor. As the Government have made it known that, after Whitsuntide, all the time of the House must be given to Government business it is pretty certain that the profession and the midwives will have another year to devise a modus vivendi.

DR. THOMAS GREGOR BRODIE, of St. Thomas's Hospital, has been elected by the Royal College of Physicians of London, to be director of the Conjoint Research Laboratories on the Embankment. Dr. Brodie was elected by

MR. HOWARD MARSH, F.R.C.S., of Bruton Street, W., is to be married in July to the daughter of Admiral Sir John Dalrymple Hay.

Dr. Edward Ward has been appointed to succeed Mr. Mayo Robson when the latter resigns the post of Professor of Surgery to the Yorkshire College on July 31st next.

MR. WILLIAM STOKER, Professor of Surgery in the College School, has announced his intention to offer himself as a candidate for a seat at the forthcoming election of Council of the Royal College of Surgeons in Ireland.

MR. EDWARD P. WILLS, who had previously given the magnificent sum of £20,000 to found the Bristol Jubilee Convalescent Home, has added another contribution of £5,000, suggesting that the total fund for endowment should not be less than £100,000, of which £80,000 have been already subscribed.

AMEMORIAL, with the signatures of Sir Jas. Crichton Browne, M.D., Sir Hy. Thompson, F.R.C.S., Mr. Anderson Critchett, F.R.C.S.Ed., Mr. E. Nettleship, F.R.C.S., &c., has been presented to the Local Government Board, with the view of stopping the degradation of charity school children by begging of passers-by on Derby Day.

Dr. Moir, who was familiarly known as the father of the Royal College of Physicians, died in Edinburgh last week at the advanced age of 91 years. Dr. Moir was born in 1808, in a French prison, where his father, a naval surgeon, who had been captured during the great war, had been joined by his wife. When his father regained his liberty, he settled in Edinburgh, and John Moir studied for the medical profession, and obtained his degree in 1828.

SIR FREDERICK McCov, Professor of Natural Science in the University of Melbourne, whose death is announced by cable, was the acknowledged chief of the scientific world of the southern hemisphere. Formerly Professor in Queen's College, Belfast, he was appointed forty years ago to the chair of natural science in the then newly founded University of Melbourne, which he has occupied ever since. He was a F.R.S., D.Sc.Cantab, and the recipient of countless honours from foreign sovereigns and scientific societies. Eight years ago he received a knighthood.

Scotland.

FROM OUR OWN CORRESPONDENT.

A MEDICAL MODERATOR.—Each year during the month of May, the Thursday on which all Edinburgh holds holiday in honour of Her Majesty's birthday, sees the inauguration of the annual Assemblies of the Church of Scotland, and the Free Church's parliaments. The Established Church representatives enter on their yearly conduct of business under Royal auspices, the Queen opening their Assembly in the person of a Lord High Commissioner; the Free Church meeting opens more quietly, but both have their Moderators, or presidents, elected for the year from among the ranks of their ministers. The Moderator of the Free Church Assembly ministers. The Moderator of the Free Church Assembly who has been thus honoured by his brethren is the well-known medical missionary, the Rev. James Stewart, M.D., Hon. F.R.G.S., of the Lovedale Institute in Cape Colony, Africa, he having been elected Moderator of the

Free Church Assembly. The friend and companion of the famous Scotchman, Livingstone, Dr. Stewart has done more than any other man for the good and welfare of the African races and against the evils of the slave trade. The election of a medical missionary to the highest office his Church can bestow is an encouraging sign of clerical tolerance and large-mindedness. Only one other medical man has, as far as we know, occupied the chair as Moderator at the annual deliberations of the Scottish Presbyterian Churches. Principal Lee, who filled the office for the Established Church about sixty years ago, possessed a medical as well as a divinity degree. Sir William T. Gairdner wrote a letter to the Edinburgh Scotsman last week, mentioning his recollections of Dr. James Stewart as a medical student, and directing attention to the interesting circumstances

attendant on his present position.

Our Infirmaries.—For some time past the Royal Infirmary has been in a state of "hot water," but it is not now singular, as another city infirmary has its bone of contention also. The directors of this latter recently appointed a deputation in order to visit a number of the leading hospitals in England and ascertain the best methods both of sanitation and antiseptic treatment. The deputation, it is stated, spent £36 on their trip and no doubt enjoyed themselves, but their pleasant dreams are being disturbed and converted into nightmares brought about by the murmurings of the staff, because the deputation consisted entirely of laymen; we certainly agree and sympathise with the staff, and it does seem a very extraordinary procedure to send a number of laymen directors on such an important errand without the inclusion of at least one of the staff, either medical or surgical, or preferably one of each. Unfortunately, the lay directors have generally the notion that the medical and surgical staff have little or no right to suggest as to improvements or otherwise in reference to the infirmaries. The surgeons are appointed for the purpose of cutting off limbs and for the treatment generally of injuries; the physicians, for the purpose of prescribing pills. potions, and boluses, and carrying out the behests of the lay members generally, but not to participate on such festive occasions or trips: they must simply be controlled and be contented with Bumble, an individual which every infirmary seems to possess.

A STRANGE CLAIM.—A person by the name of John Lamb Thomson raised an action against Dr. Devon, Medical Officer of H.M. Prison, Glasgow, claiming £500 as damages for an assault alleged to have been committed on him by the defender on December 20th, 1897, when the plaintiff was a prisoner in Duke Street Prison, Glasgow, the assault consisted in the plaintiff while a prisoner being vaccinated by the defendant. The trial lasted four days, and the sheriff-substitute found in favour of the defendant with expenses. To this decision the plaintiff appealed, and the sheriff has confirmed the decision of the sheriff-substitute, and with additional expenses.

Obituary.

JOHN MOIR, M.D., F.R.C.P.E., F.R.S.E., OF EDINBURGH.

EDINBURGH has just lost the doyen of her medical men, the late Dr. John Moir, at the advanced age of 91 years Born in prison, his after-life belied such an inauspicious beginning. His father was a naval surgeon, and in 1808 was a prisoner of war in the French fortress of Verdun, where his wife had joined him some time before, to share his trials. In 1827 John Moir obtained the licence of the Royal College of Surgeons of Edinburgh, and a year later, when 20 years of age, became an M.D. of Edinburgh University, becoming a Fellow of the Royal College of Physicians in 1837. For many years he was one of the leading obstetricians in Edin-burgh, and even up to a short time before his death interested himself, despite his burden of many years, in medical matters and philanthropic schemes. deeply religious temperament, he was an energetic adherent of the Free Church of Scotland, and a moving spirit in all missionary ventures. He was one of the

original founders and directors of the Edinburgh Medical Missionary Society, indeed with his death the last of the original directors has departed this life, while the names of some of his sons are enrolled among the most successful medical missionaries trained and sent out by that excellent institution.

John Moir performed his life's long work without fear and without favour; an honest, trustworthy physician, content to win the regard of men by upright and honest endeavour rather than by any striving after personal

publicity.

MR. H. B. HEWETSON, F.R.C.S, F.L.S., OF LEEDS.

The death of Mr. H. B. Hewetson, ophthalmic and aural surgeon to the Leeds General Infirmary, removes not only a surgeon whose work was well known in the provinces, but one who gained for himself a wide reputation for his knowledge of that most fascinating of subjects Natural History. He was a Fellow of the Linnean, the Royal Geographical, and the Zoological Societies, as well as a member of the Ornithological Union. Furthermore he was an artist of some repute, and found time to do much travelling. No one could have taken up so many subjects in science and art, as the late Mr. Hewetson did, and excel in them, without having an abundance of natural gifts; hence, in his way, he was a genius, and his loss, therefore, will be the more keenly felt by all of those who profited by, and valued, his acquaintance. The gap in the community which he has left will be a difficult one to

Correspondence,

We do not hold ourselves responsible for the opinions of our

THE "DOSSIER SECRET" OF THE LONDON CHAMBER OF COMMERCE.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—The London Chamber of Commerce holds a secret inquiry, the names and the precise allegations of the witnesses are not published, and no facility is afforded for cross-examination, even so much as would bear on the bona-fides and respectability of the witnesses. This is precisely the procedure that has paved the way to all the lies, forgeries, and wickednesses of the Dreyfus affair—yet on evidence not an iota more trustworthy than that for which Dreyfus was sent to the Devil's Island the London Chamber of Commerce, with a colossal disregard for the most elementary principles of fairness and common courtesy, make certain grave accusations which cannot be, or at any rate have not been, substantiated.

Allegations made by a body of men so impervious to reason and fairness may well be disregarded. They may be sincere, but are indiscreet in their action, or it may be merely the proverbial red herring to divert public

attention from the Chamber itself.

I am, Sir, yours truly, A Non-Commissioned Practitioner.

THE BIRMINGHAM CONSULTATIVE INSTI-

TUTION. To the Editor of THE MEDICAL PRESS AND CIRCULAR.

Sir,-Judging from the tone of Dr. Saundby's letter in a contemporary he evidently thinks that no one outside the Midland metropolis is entitled to make any remarks

on the question at issue.

The Hospital Reform Association, with the idea of lessening the amount of abuse that exists, more especially in the special hospitals and in the special departments of general hospitals, made a definite recommendation to the effect that it was desirable to provide an Institution where people of moderate means could obtain the advice of specialists at a reduced fee. The Council were of opinion that such an irstitution should be established on strictly business lines, and that to prevent well-to-do people from obtaining advice at it it should be made an absolute rule that every patient should bring a note from a medical man, stating that he

(or she) was not in a position to pay the ordinary fee of consultants.

As one who has watched the attitude taken up by many of our hospital physicians and surgeons, one cannot help noticing the amount of zeal thrown into the opposition to this proposed Consulting Institution by the leading consultants of Birmingham, and compare it with the apathy shown by the same gentlemen when the question of hospital reform was brought under their immediate notice a year or two since. As I remarked in the Birmingham Daily Post, the idea of paying his consultants a fixed sum per annum for their services is most objectionable and ought not to be permitted.

I may remind you that Birmingham is a city where the percentage of out-patients to the population is a very high one; and also that in spite of a very efficient and exhaustive inquiry in the year 1892 little or nothing has been done to reform the system of out-patient I am, Sir, yours truly, T. GARRETT HORDER.

Cardiff, May 20th, 1899.

THE APPOINTMENT OF POOR-LAW OFFICERS.

We have received from Drs. Crowley and J. Basil Hall a communication in which they point out that in reference to the meeting convened by "The Bradford and West Riding Medical Union,"

1. The meeting was not representative. Invitations in several instances were omitted, and the majority of practitioners of any position took no part in the proceedings.

2. The Bradford and West Riding Medical Union is not representative nor, indeed, recognised as anything more than a society recently got up by Dr. Hime in opposition to an old standing medico-ethical society with which he has quarrelled.

3. The committee of the older society (Bradford Medico-Ethical) has met and discussed these appointments, and decided that no steps should be taken in the

4. That neither Dr. Crowley nor Dr. Hall is on this committee.

Parliamentary Aews.

Examinations in POST-MORTEM SCOTLAND.— In answer to a question by Sir William Priestley, the Lord Advocate stated that in Scotland no person except the medical men instructed to conduct the necropsy is allowed to be present at a post-mortem examination except with the consent of Crown counsel or on the order of the sheriff. Crown counsel may, in their discretion, sanction the presence of a medical man who has attended the case or in the interests of the accused; but this is done only on condition that he is to be present merely as an onlooker, and is not to interfere in any way with the Crown examination. No formal intimation is given that a necropsy is to be held, but in all cases where any person is in custody on suspicion of causing death a necropsy is made as a matter of course, so that an accused person or his advisers cannot be in doubt as to the necessity of making immediate application for permission to send a nedical man to witness the necropsy if they so desire it. The quarter to which application should be made is the Procurator-Fiscal, whose duty it is in all cases of urgency to communicate by telegraph with the Crown Agent for the instructions of Crown counsel. If an independent post-mortem examination is desired it can be made after the Crown examination.

THE MIDWIVES BILL has once again been postponed. The date assigned for the discussion is May 31st—the

Derby Day. Absit omen!
ISOLATION HOSPITALS ISOLATION HOSPITALS (AMENDMENT) BILL.—The Isolation Hospitals (Amendment) Bill amends and extends the Act of 1893, by giving District Councils and joint Boards power to transfer to County Councils any hospital provided under the Public Health Act., 1875, or any local Act, and to empower County Councils to

raise the necessary funds for structure and establishment expenses on the security of the county rate. Lord Lichfield strongly supported the necessity for some such measure, and Lord Harris, on behalf of the Government. gave the Bill a qualified support, and the second reading was carried on the understanding that the committee stage would be deferred till after Whitsuntide.

The Oysters Bill.—Lord Harris's Bill enabling

County Councils to inspect oyster beds and to analyse the water in which the oysters are laid, was read a second time. The Councils will have power, if they judge neces-sary, to prohibit the removal of oysters from a given area for a period of ten days, the proprietor of the bed having the right to petition the Local Government Board on the merits. Other clauses provide penalties under the Act, and there is a special clause dealing with foreign oysters that might have been subject to contamination.

Laboratory Aotes.

ESVACH WATER.

This is a valuable aperient water containing a considerable proportion of sodium and magnesium sulphates, to which, in the main, its action is doubtless due. These salts, when administered alone, are unpleasant in taste, and usually have so disagreeable an effect owing to their griping action as to render them unpopular as a medicine. In the case of the newly-introduced aperient water, "Esvach," this objection has been successfully overcome without interfering with its medicinal proper-ties, owing to the presence of a considerable proportion of bi-carbonate of soda. This salt in conjunction with the magnesium sulphate no doubt gives rise to magnesium bi-carbonate, and the result is that not merely is the taste of the water far less bitter than would otherwise be the case, but the value of its aperient properties is materially enhanced.

In our analysis we found the total solid residue, obtained on evaporation of the water, to be 4.87 per cent., and the constituents are approximately follows:-Magnesium about 100 per cent., carbonic anhydride, 11 per cent., sulphuric acid (calculated as SO4) 6000 per cent., the remainder consisting essentially of salts of sodium with small quantities of other salts.

As the water is an active aperient it is well adapted for the use of travellers, seeing that a moderate dose will produce the required effect. The sole wholesale agents for this water are Messrs. Davy Hill and Son, Yates and Hicks, 64 Park Street, Southwark.

VIBRONA SHERRY.

VIBRONA SHERRY, samples whereof we have received from Messrs. Fletcher, Fletcher and (o., is a combina-tion of the neutral hydrobromates of the cinchona alkaloids in a pure dry sherry of the Amontillado type. The wine is of light alcoholic strength, and is exceptionally free from sugar, and its tonic and appetite-giving properties will be appreciated by those who object to the comparative sweetness of analogous preparations with a basis of Madeira. The presence of the alkaloids as hydrobromates enables this tonic wine to be taken without fear of inducing cinchonism even by persons with an idiosyncrasy in that direction. Vibrona Sherry has a delicate flavour with a grateful bitterness, and should be especially serviceable to persons of gouty or dyspeptic tendencies.

Medical Rews.

The Canadian Medical Association.

The next annual meeting of the Canadian Medical Association will be held at Toronto on August 30th, 31st, and September 1st next. The President will be Mr. Irving Cameron. The meeting promises to be an important one, inasmuch as the final details will probably be decided on in connection with the scheme of medical registration throughout the Dominion. This is a matter, of course, of supreme importance to the colony generally. Dr. F. N. G. Starr is the Secretary of the Association.

Medical Exhibition.

THE Medical, Surgical, and Hygiene Exhibitors Association opened their annual exhibition of objects and appliances germane to medicine and the allied sciences, at the Queen's Hall, Langham place, W., yesterday (Tuesday), and it will remain open until Friday, 26th

Injuries from X-rays.

An important case against X-ray operators is shortly to come before the courts in Chicago. In 1896 the plaintiff sustained an injury which affected his ankle, and he submitted it to the X-ray operators. He claims that the apparatus was improperly handled, for he received a serious burn which necessitated the amputation of his foot. The claim is for 25,000 dols. damages. A similar case resulting from the use of the X-rays occurred in Paris a short time since to a young woman. It was necessary to have three exposures, and after the third somewhat severe lesions appeared on the skin causing a long illness, and the doctor was sued for 5,000 francs, and the matter has been referred to a committee of experts. The moral is that skiagraphers had better be prudent until experience has sufficiently demonstrated the latent capabilities of their apparatus for good and

Death Under Chloroform at Dudley-

An inquest was held at Dudley last week on the body of a man, æt. 35, who died while chloroform was being administered prior to his being operated on for strangulated hernia. It was stated that not more than two lated hernia. It was stated that not more than two drachms of the anæsthetic had been given, and the medical evidence favoured the view that death was due to sudden dilatation of the heart. We are not told how the chloroform was given, whether by means of an inhaler or by the pernicious "open" method; but the chances are great that it was flopped on to a towel and held over the patient's face. The usual verdict was returned.

Scholarship for Medical Research.

THE Technical Education Board of the London County Council is co-operating with the Asylums Committee in offering a scholarship of £150 a year, tenable for two years, for students of either sex (preferably qualified practitioners), to enable them to carry on investigations into the preventible causes of insanity, the scholar to carry on investigations in the pathological laboratory attached to Claybury Asylum. A similar scholarship has been held during the past two years by Dr. J. O. W. Barratt, who has carried on valuable original investigations into the causes of insanity, many of which have been recently published. Dr. Barratt has recently been appointed pathologist at the Wakefield Asylum, and the scholarship which he has held is therefore vacant. Candidates must be resident in London. Application should be made to the secretary of the Technical Education Board, 116, St. Martin's Lane, W.C., not later than Wednesday, June 7th.

Death from Anthrax.

An inquest was held at Liverpool on the 16th inst. on the body of a man employed by a tanner, who died from anthrax. It was stated that the deceased had been engaged in "fleshing" hides from China, which, before being dealt with, were treated with carbolic acid and bleaching powders. The handling of Eastern hides is recognised to be particularly dangerous, and this is the second death from anthrax at Liverpool under similar circumstances during the last few weeks.

Naval Medical Service.

THE undermentioned gentlemen who competed on May 8th and following days at Examination Hall, Victoria Embankment, for appointments as surgeons in the Royal Navy, have been granted commisssions:-

Rotices to Correspondents, Short Letters, &c.

CORRESPONDENTS requiring a reply in this column are particularly requested to make use of a distinctive signature or initials, and avoid the practice of signing themselves "Reader." Subscriber," "Old Subscriber," &c. Much confusion will be spared by attention to this rule.

REPRINTS .- Authors of papers requiring reprints in pamphlet form after they have appeared in these columns can have them, at half the usual cost, on application to the printers before the type is broken up.

LOCAL REPORTS AND NEWS .- Correspondents desirous of drawing attention to these are requested kindly to mark the newspapers when sending them to the Editor.

ORIGINAL ARTICLES or LETTERS intended for publication should be written on one side of the paper only, and must be authenticated with the name and address of the writer, not necessarily for publication, but as evidence of identity.

EFFECTS OF EDUCATION.

A PATIENT the other day called on the doctor of his society to explain why he was not at home when the latter called to see him about the rheumatism of the feet from which the sick member suffers. Patient: You see I went down to the "Central," not the Central police office, but the Central electric station to get a few shocks to see if it would do my pains any good. Doctor: Well: and how did you stand the sheeks? Did you bear them well? Patient: Oh, yes; for the person who has charge of the electric current told me that he had applied five rampires to each foot, and for a good long time, and I never flinched; in fact, he had never known anyone to stand so many rampires before without singing out.

RUSTICUS.— Croup is a general term you had better avoid. However, if you must use it in deference to popular usage, you had better reserve the term "true croup" to diphtheria of the larynx, and false croup to catarrhal laryngitis. Both are dancerous conditions, of course, and want active treatment. The diphtheritic form is by far the more serious, but operation mortality is now much reduced by the antitoxin injections. Your question is important, although we doubt if the term croup (really a symptom) will be rooted out of the vernacular for ages to come.

be rooted out of the vernacular for ages to come.

F. O. SMITH.—1. Certainly; with pleasure. 2. Half an ounce of carbolic acid almost always fatal. Wash out stomach with Epsom salts, and give half-ounce doses of sulphate of macnesia and sulphate of soda. The soluble sulphates combine with the carbolic acid to form harmless sulpho-carbolates. Olive oil in large doses -e.g., a couple of wine-glassfuls. The 1-50 grain of sulphate of atropine may be given hypodermically. The sale of this substance ought to be restricted, as the numbers of suicides and accidental deaths through its agency are very great. We can hardly be said to have a really satisfactory antidote yet for this poison. 3. Send us notes of the case by all means, and the fuller the better. We are always glad of terse, practical clinical experiences.

Meetings of the Societies and Tectures.

THURSDAY, MAY 25TH.

DERMATOLOGICAL SOCIETY OF GREAT BRITAIN AND IRELAND (20, Hanover Square, W.).—4.30 p.m. Annual Meeting. Mr. Jonathan Hutchinson will read a Paper and open a Discussion on Diseases of the Nails with special reference to their Significance as Symptoms.

THE TREATMENT OF GONORRHŒAL SALPINGITIS. (a)

By J. W. TAYLOR, F.R.C.S.,

Surgeon to the Birmingham and Midlards Hospital for Women, Consulting Surgeon to the Wolverhampton Hospital for Women.

(Concluded from page 532).

THE view of the disease and its treatment which I have presented for your consideration has not only its medical but also its surgical aspect.

If we may hope for some radical control of pelvic gonorrhea from medicine not only will operation be less frequently necessary, but partial operations which were formerly derided and stigmatised as useless will find a legitimate use, and prove, in conjunction with medical means, a higher and better method of treatment than that of complete removal of the appen-

dages so strongly urged in former years.

For instance, the free opening of pus-cavities without ablation of the uterine appendages or the removal of a pyo-salpinx of one side only when the tube and ovary of the opposite side are so far free from disease and perfectly healthy, may be good practice, and is sound in principle if we can guard

against the extension of disease.

As an adjunct or handmaid to surgery, tooafter operation has been performed—the specific treatment of the patient may sometimes ensure a success that otherwise might be wanting. When the wound refuses to heal, the stitches are ulcerating outthe drainage track is sloughing—the temperature hectic and the appetite wanting-when the case seems slowly going to the bad some two or three weeks after the immediate danger of the section has been successfully passed (a not very uncommon sequel after abdominal section for pelvic gonorrhœa with abundant pus-formation and almost confined to this class of case), the power of the biniodide to im-prove the condition in my own hands has been marked and almost immediate in its action.

If my contention is right, we may hope from the use of specific treatment, for a selective action in cases before operation-limiting the necessity of the latter—for a freedom of choice that was formerly unknown during operation of various methods more or less conservative, and finally (after operation) for its influence as an aid to recovery that may materially improve both immediate and remote statistics.

This brings me to the consideration of pyo-salpinx

and its treatment.

I incline to the belief—based mainly, perhaps, on clinicaland operative observation—that dangerous pyo-salpinx is but rarely a purely gonorrhoad disease, that it is usually a product of mixed infection, and that the more dangerous element comes from the intestinal

It is always—or nearly always—started by gonorrheal inflammation, but so long as it remains a sac of purely gonorrhoeal pus it is usually small and only rarely dangerous. But as the pus-sac enlarges it

(a) Paper read before the British Gynrecological Society, May 11th, 1899. For discussion see page 535—last No.

comes into immediate relation with the bowel and usually with the sigmoid flexure and rectum. The pus-sac is infected from the neighbouring bowel—like a broad-ligament pregnancy under bowel—like a broad-ligament pregnancy under similar conditions—the condition becomes urgent, the patient cannot sleep for pain, and the temperature, though sometimes unreliable, may rise to high

Then operation is needed, and no unnecessary delay is permissible, and the operation I wish to recommend with the utmost force of which I am capable is that of posterior vaginal coliotomy—the thorough opening of the pouch of Douglas from the vagina—the digital and bi-manual exploration of the tumour or tumours from this situation, the tapping of all puscavities deliberately carried out, the enlargement of all openings thus made, and the establishment of pelvic drainage from all infected parts by a tampon or tampons of iodoform gauze

If this operation is done as I have advised—by free incision (no puncture or simple tapping is sufficient), the urgent symptoms are at once and thoroughly relieved, a condition of imminent danger of death is converted sometimes as if by magic, into one of peace-

ful rest and happy convalescence.

The maximum of relief-I speak advisedly, for the peritonitis following removal of a double and adherent pyo-salpinx is often severe, and the after result in no way better than that attained by the operation I am advising—the maximum of relief is attained with the minimum of danger and the minimum of injury to the sexual organs concerned. I have repeatedly employed this method of treatment during recent years and have followed it up in most cases (so far as I have been able to do so) by specific treatment. In each of these cases I have been more and more satisfied with the efficiency of the means employed and impressed with the vast superiority of this operation to the removal of the tubes by abdominal section.

The following cases may be taken as recent examples

of its value.

Mrs. I., æt. 28, had been married four years. Her husband confessedly had contracted gonorrhoa since his marriage. Six weeks ago the patient had a green discharge from the vagina, and for four weeks had suffered with severe abdominal pain.

I saw her on the evening of May 25th, 1898, in

consultation with Dr. Miligan.

She evidently had some general acute peritonitis. The abdomen was distended and tympanitic; the legs drawn up. She had frequent vomiting, a pulse of 120, and a temperature of 103 degs. F. She was very feeble, very restless, and crying with pain. On vaginal examination a mass was found in the pouch of Douglas, and pushing the uterus to the left. tumour was acutely tender. A dose of calomel was ordered to be given at once, followed by frequent enemata, and it was arranged to move the patient to my house for operation on the following day. On May 27th I opened the pouch of Douglas, separated adhesions, and evacuated a large quantity of foul The abscess pus from the right Fallopian tube. cavity was washed out and packed with iodoform gauze

In the evening her pulse was 96. She was comfortable; her bowels had been opened with a simple

enema, and she had a fairly good night's rest afterwards, "the first good night for weeks." The patient

made a good recovery.

Mrs. J., æt. 24, married four years, came to my out-patient room on August 25th, 1898, complaining of abdominal pain and dyspareunia, which had been increasing for six months. On examination I found what I took to be an enlarged and tender left overy that was evidently the source of the pain complained of. I ordered a mixture of bromide and viburnum,

and gave some general hygienic advice.
On October 27th, the patient was brought to the hospital evidently suffering from intense pain. She was crying, and stated that she had had no sleep for four nights on account of this Her temperature was 101 degs. F. On again examining her I found a fixed tender mass to the left of the uterus pushing the latter to the right. This was acutely sensitive to touch, and I believed it to be caused by a distended tube. On closer inquiry into her case I found that there was a distinct history of copious purulent vaginal discharge some three years ago. I altered the diagnosis to one of acute pyo-salpinx, and admitted her into hospital Operation was done on October 31st. I opened the pouch of Douglas through the posterior fornix and evacuated some dirty and rather foul serum from the pelvis. On examination through the opening thus made I found the left tube was dilated into a large pus-sac, having thick walls, and being very adherent. I first tapped this with a trocar and cannula, and afterwards opened up the punctured incision with my fingers. One or two secondary collections of pus were also set free. The cavities were

sponged out and packed with iodoform gauze.

The patient, who had been before the operation almost a type of misery, immediately altered. In the morning she was smiling, happy, and good-tempered, and said that she had passed the best night she had had for several weeks. She has made uninterrupted progress, and leaves the hospital to-day.

I do not wish it to be inferred that I regard posterior vaginal coeliotomy as the only operation to be undertaken in pyo-salpinx. When the tumour is large and prominent or "presenting" towards the abdominal aspect, abdominal section may prove a better means of access to the seat of mischief. Wherever this seat of mischief is most accessible, there is, in nine cases out of ten, the best point of attack.

I will not, however, dwell on this part of my subject, but pass on to the consideration of the limita-tions to success in the treatment of gonorrheal disease, and any means we possess of avoiding them. These may be shortly considered under three heads:—

1. The severity or complications of the disease

preventing recovery.

2. The carelessness and distaste of the patient for any prolonged treatment.
3. The effect of adhesions in causing sterility and

occasional pain.

1. The first is undoubtedly the most important. In spite of all that may be done in the future I quite believe that there will remain a residuum of intractable cases, and among these I would particularly point out cases complicated with uterine fibroid or anything which tends to cause or increase uterine hæmorrhage. When bleeding is severe no patient or medical attendant will continue a course of treatment which is not immediately directed to the stopping of the hæmorrhage. In addition to this, both mercury and iodides in some people appear to increase the tendency to bleeding. In all of these cases 1 recommend vaginal hysterectomy, with or without removal of the appendages. It is not only the most rational operation in theory, but is productive of the best final results when conservative surgery is hopeless.

2. The carelessness and distaste of the patient for treatment will often be an annoying feature and source of failure, as it is so often in syphilis. In some cases the biniodide mixture causes nausea, and even vomiting. When this is the case smaller doses may be tried, or recourse may be had to a method of may be tried, or recourse may be had to a method of treatment, which is occasionally very useful. Only one dose of iodide is given in the day, but this is a large one—from 15 to 20, 30 or 40 grains. This is taken the last thing at night before going to sleep. Every other night, or every night if necessary, a Plummer's pill (pil. hyd. subchlor. co.) is taken at the same time. The patient keeps all her medicine in her bedroom, and only needs to remember it on setting to rest. retiring to rest.

3. The effect of adhesions as a limitation to full recovery is a more important matter. Occlusion of tubes and peri-tubal adhesions, consequent on gonorrheal salpingitis, do not partake themselves of any specific character and must be regarded rather as secondary mechanical results of the inflammation which has been caused by the pelvic gonorrboa, differing in no essential from peritoneal adhesions elsewhere, such as those caused by injury, by

appendiciti-, or by gall-stones.

Their absorption and disappearance will not, therefore, be secured by the cure of the gonorrhosa. The cure of the gonorrhoea will be the necessary pre-liminary, but the actual disappearance of adhesions will probably depend on the perfection of the general health and the power of relative mobility enjoyed by

the adhering organs.

As a necessary consequence it will, I believe, be found that sterility will still result or persist when the appendages of both sides have been attacked by disease before any treatment has been begun. But if energetic treatment is started when only one side is affected and the opposite tube is healthy, one may reasonably hope that the healthy tube will remain healthy and the patient retain her fertility. Such isthe explanation, I believe, in both of the cases I reported at the beginning of my paper, in which conception took place at a period subsequent to the salpingitis, while in the acute case of pelvic gonorrhoea, notwithstanding the comparatively short duration of her illness, both sides have suffered and future fertility is hardly to be expected. I shall be interested to watch this case and see if my forecast is.

For similar reasons a remainder of occasional and slight pain may be rather frequently expected in the most favourable cases—such a sequel as is often met with after an ovariotomy from adhesions to the stump. This depends mainly, I believe, on the involve-ment of intestine or omentum in attachments. If these escape the patient has no pain—if they are

involved, the patient may have occasional discomfort

and sometimes acute, if transient, colic.

The consideration of this subject would not be complete without some reference to prophylaxis, and to the treatment of acute and chronic gonorrhoeal vaginitis. In the acuter forms of gonorrheal salpingitis when: specific vaginitis and endometritis are also present, and in gonorrhoal vaginitis when it may still be possible to limit the upward spread of the disease, local treatment is of very great and indeed of primary importance.

As regards the gonococcus, the strongest and best local germicides known (according to Neisser) are the nitrate of silver, the perchloride of mercury and ichthyol, and it is on one or more of these that chief

reliance should be placed.

In all cases of acute gonorrheal salpingitis in which the uterus and vagina are also affected, I use a vaginal suppository of ichthyol (10 per cent.) every night and a douche of crude acetic acid during the

day. In cases of complicated gonorrheal vaginitis, especially in hospital practice, I generally use a vaginal suppository of silver nitrate (gr. 1) every night, and the same vaginal douche of pyroligneous acid (3ss. and Oj) twice during the day.

If, as only very rarely happens, the patient comes almost immediately after exposure to contagion it may be advisable to disinfect the vulva, vagina, and

cervix manually, as in a vaginal coliotomy.

In one case of vaginitis of about two days' duration, in which the patient was already feeling considerable and rapidly increasing discomfort, but in which, it is only fair to say, the gonorrhead origin was never thoroughly established, I did this with the very best result. The disinfection was repeated three times, and the patient was directly cured with no retension

In cases where there is no evidence of endometritis or tubal disease the local treatment advised contains all that is required, and this should be applied in the simplest possible manner. No unnecessary examination should be made, and the use of the sound should

be forbidden as most dangerous.
It is only in cases of tubal disease, where the appendages are evidently affected by gonorrheal inflammation, in gonorrhoal rheumatism or arthritis, in gonorrhoal endocarditis, or in persistent and incurable discharges due to gonorrhea, that the local treatment must be supplemented by the administra-tion of mercury and iodides, as described in the earlier sections of my paper.

To emphasise and make ready for discussion the main points contained in this communication, I have prepared a short abstract, or précis, of the propositions I am disposed to maintain, and on which I

invite the criticism of my colleagues.

First.—That a large number of women who are suffering from tubal disease have been at some time or another exposed to the infection of syphilis as well as of gonorrhea. That these undoubtedly show marked improvement after a prolonged course of mercury and iodides, and in the course of this treat-ment unless acute pyo-salpinx intervenes (in which medicine is useless) it is the rule rather than the exception for all gross physical signs of disease to slowly and permanently disappear. Secondly.—That many cases in which there is no

history of syphilis, including cases in which there is the unmistakable history of gonorrhea, pure and simple, as the sole cause and starting-point of tubal disease, do similarly improve and get permanently well under the same course of treatment, provided always that the disease stops short of acute pyo-sal-

pinx and its dangerous complications.

Thirdly.—That acute pyo-salpinx is peculiarly liable to occur in the first place on the left side of the body, and its special severity is probably due to secondary infection from the rectum. That cases of pyosalpinx, whenever possible, should be treated by free incision of the posterior vaginal fornix, by thorough exploration and emptying of all pus-cavities from the pouch of Douglas, and by iodoform gauze drainage. That this is far preferable to the older operation of removal of the appendages which is not only much more dangerous, but is peculiarly liable to be followed by fæcal fistula, an operation-sequel sometimes worse than death itself.

Fourthly.—That such cases of mixed infection and acute suppuration treated by operative evacuation of the pus, with or without removal of the appendages, do sometimes not only recover but remain permanently well without further treatment, the acuteness of the inflammation appearing to terminate the process of infection. In other cases, recovery is not so complete or relapses are met with, and these cases should be followed up by a course of specific treat-

ment, the beneficial result of this being often imme diately manifest when the wound tissues are unhealthy and the healing is delayed.

Fifthly.—That occlusion of the tubes and peritubal adhesions consequent on gonorrhoal adhesions have no direct specific causation, and must be regarded rather as secondary mechanical results of the local peritonitis which has been caused by salpingitis.

Their absorption and disappearance will not therefore be necessarily secured by the cure of the gonorrhoa, and sterility may persist although gonorrhoa is entirely eradicated from the system.

Sixthly.—That in gonorrhea of the pelvis there will probably remain a residuum of intractable cases, particularly cases of complication with other diseases such as fibroids of the uterus. That in these cases operative removal of the organs affected will still be required, and that vaginal hysterectomy whenever possible, with or without extirpation of the uterine appendages is not only the most rational operation in theory, but is productive of the best final results.

CONSIDERATIONS AS TO THE ETIOLOGY AND SIGNIFICANCE OF DILATED HEART. (a)

By H. A. CALEY, M.D.,

Physician to Out-Patients, St. Mary's Hospital, &c.

BEFORE discussing the etiology of pathological dilatation of the heart the author alluded to dilatation of the heart under physiological conditions of the circulation. Reference was made to the work of Roy and Adams, Starling and others, with a view to showing that whilst within certain narrow limits the dilatation induced by some exertion might be a mechanical advantage in relation to the ventricular output, these limits were soon passed, and the dilatation was then an evidence of heart-fatigue. This might be prematurely induced by the strain to which the heart muscle was subjected being excessive, or by the heart muscle itself being out of condition, but it was especially easily produced if both factors were combined; and under such circumstances a condition which was in the first instance physiological might very readily pass into dilatation which was definitely pathological.

The important principle in relation to dilatation under physiological conditions of the circulation was that the liability to its occurrence depended upon the inter-relation between (1) the element of increased mechanical strain leading to increase of intraventricular pressure; (2) the condition of the myo-

cardium at the time being.

In respect to dilatation under pathological conditions, the element of mechanical strain as a factor in its causation was first considered. The principal causes of increased intra-ventricular pressure were referred to, and it was pointed out that in addition to the primary effects of the increased strain, owing to alterations in the physical condition of the heart, certain additional factors had to be considered, more especially the consequences of increase of residual blood in the ventricles, and the effects of tension on a muscular sphere or spheroid like the ventricle. Variations in the coronary circulation and the relation between the blood pressure in the systemic circuit and that in the coronary area must also be borne in mind. Dilatation, in the causation of which myocardial weakness was the primary and predominant factor was then considered, reference being made to the dilatation of acute specific diseases, with or with-

⁽a) Abstract of paper read before the Harveian Society of London, May 18th, 1899.

out actual myocarditis, to fatty and other forms of degeneration, senile myocardial weakness, the dilatation of nervous and general debility, of some forms of anæmia and that due to toxic causes such as alcohol and tobacco, and probably also to toxic substances present in auto-intoxication of gastro-intestinal origin. The differences in the degree of dilatation from these various causes were discussed, and stress was laid on the fact that in relation to prognosis the degree of dilatation must always be considered in conjunction with the condition of the heart muscle with which the dilatation was associated. Whilst chronic dilatation might be due to increased strain alone, or to primary myocardial weakness alone, in the most severe forms of dilatation both factors were frequently combined, and the principle enunciated in connection with physiological dilatation was similarly illustrated in the case of pathological dilatation, namely, that the essential point was the inter-relation between the element of mechanical strain and the condition of the myocardium at the time being Even in cases in which the element of increased mechanical strain was the chief factor in the causation of the dilatation, its later developments were often traceable to the supervention of myocardial changes. The latter part of the paper was devoted to the significance of dilatation. Just as physiological dilatation (beyond certain narrow limits) was an evidence of heart fatigue, pathological dilatation was an evidence of heart over-strain, past or present, and frequently the precursor of heart failure.

In disease, as under physiological conditions, it was broadly true that the heart's power of doing work was in inverse ratio to the degree of dilatation, but the greater the deviation from the comparatively simple conditions of a healthy heart dilated by excessive strain, the less could reliance be placed on the degree of dilatation as per se a gauge of the severity

of the lesion.

In order to estimate with any approach to accuracy the significance of any given case of dilatation, attention must be given to the degree of dilatation, the condition of the myocardium with which the dilatation was associated, its precise etiology (with especial reference to the retention of the cardiac dilatation to the general health, and the relative importance of the mechanical and myocardial factors in its production), the extent to which the dilatation interfered with the work of the heart in relation to the general circulation, and the degree of recuperative power, as evidenced by the course of the case and the effects of treatment. A broad view on lines such as these was essential if the extremes were to be avoided of making too much or too little of any given case of cardiac dilatation.

ON UTERINE CANCER AND ITS TREATMENT. (a)

By Thos. MORE MADDEN, M.D., M.R.C.P.I., F.R.C.S.Ed.,

Obstetric Physician to Mater Misericord'æ Hospital, Publin.

THE author referred to the increasing frequency of malignant diseases of the uterus, and more especially to the various methods available in their treatment, as employed in his wards in the Mater Misericordiæ Hospital, Dublin, where, during the past twenty-five years, upwards of a hundred cases of this kind have come under observation. Within the last six years there were 31 cases of uterine carcinoma and 12 instances of vulval or vaginal malignant disease, or 3 per cent. of the former in a total of 1,054 gynæcological cases. In the preceding five years there were 23 cases of uterine and 11 of vulval

(a) Abstract of paper read at Royal Academy of Medicine in Ireland, April 21st, 1899.

or vaginal malignant disease noted, and in his earlier 14 years' service there a somewhat similar proportion was observed. Confining himself now, however, to the last eleven years referred to, the general origin of uterine cancer in the cervix was shown in 47 of these 54 cases. Its connection with parturition or lacerations was evinced by its occurrence in 39 childbearing women and in only 15 nulliparous or unmarried. While the predisposing influence of age was shown by the fact that 36 of these patients were from 40 to 55 years of age, 10 were beyond the latter period; 8 were under 40, and of these one was an instance of medullary carcinoma uteri in a girl only 16 years old. The writer lays special stress on the vital importance of the early recognition of this disease by local investigation as well as by microscopic examination of specimens removed by curetting in every instance of possibly adenomatous or cancerous disease of the uterus. He believes that disease to be primarily developed in the cervix in the vast majority of instances. Moreover, he holds that it frequently remains localised there for a sufficient period to permit its complete and effectual cure by the timely amputation of the cervix, which, followed by the application of the actual cautery to the wound so produced, he regards as the safest, most effectual, and reliable method of treatment in such cases. In exemplification of this the following facts are adduced from cases in which Dr. More Madden removed the cervix for cancer, and subsequently traced the after-history of the patient. In 31 instances in which the cervix was thus amputated there was no mortality consequent on the operation; in one of these, however, the disease returned in the uterus four months subsequently; in 5 cases it returned there or elsewhere within a year; in 2 within two years; in 1 within three years; and in 1 nearly four years after operation. But, on the other hand, in 10 cases there was no return within a period of four years, and in some there was no recurrence ten years after the amputation of the cervix; in 5 cases the information was limited to two years, and in 6 to one year, and indicated no return of cancerous disease within these periods. These results immediate and remote, may be contrasted with those obtained by hysterectomy for cancer, whether by vaginal or abdominal methods. The writer's experience not only shows no direct mortality from the amputation of the cancerous cervix, but also shows that twothirds of the patients so operated on were free from recurrence of cancer at the expiration of the subsequent periods mentioned. Can any better results, or any results as good be claimed for hysterectomy under similar circumstances? Therefore, only in cases where cancer has distinctly originated in the fundus or body of the uterus, or in instances of carcinoma which has extended upwards from the cervix, and then merely as a palliative measure to relieve great suffering, and possibly prolong life for a little, does hysterectomy appear to him justifiable. In but one of the cases of the latter kind in which the writer was then forced to resort to hysterectomy, was the patient still alive and apparently well at the end of two and a half years subsequently, in other remaining cases the disease recurred earlier in other organs. For the relief of pain in cases of inoperable uterine cancer, Dr. More Madden recommends conium and orthoform, and advises special caution in the use of morphia and opiates. To mitigate the fœtor of discharge he relies on terebenthene injections, peroxide of hydrogen and a one per cent. solution of formalin. As local applications in open carconoma he has experienced most benefit from the employment of celandine and methylene blue. Electrolysis, though recommended by others, had failed in his hands. Finally, he sums up his experience of the treatment of this disease, in hospital and private practice during more than a

quarter of a century, by saying that up to the present the best possible prospect of the cure of uterine -cancer rests, as a general rule, in its early detection and prompt removal by the cervical method described in this communication.

DILATATION OF THE STOMACH.

WITH ESPECIAL REFERENCE TO

ETIOLOGY AND TREATMENT. (a) By JOHN A. LICHTY, M.Ph., M.D.

THE term, "dilatation of the stomach," has of recent years been surrounded by considerable obscurity. The most satisfactory classification of this condition is that given by Pepper and Stengel as atonic dilatation and obstructive dilatation. These terms define themselves. They are also in accord with the classification of Riegel and Boas, who speak of:-1. Simple gastric atony, or motor insufficiency, or myasthenia without dilatation. 2. Atonic dilatation without pyloric stenosis. 3. Secondary dilatation (motor insufficiency due to pyloric stenosis).

In this paper, atonic dilatation, in its broadest sense, will be considered with special reference to its

etiology and treatment.

For the purpose of study, the causes of atonic dilatation may be divided into two groups. The first group includes the direct, or mechanical causes; the second, the indirect, or nutritional causes. Clinically, however, this classification is of little consequence, for rarely will it be found that a dilated stomach is due to a single cause, or that the causes

may even be found under a single group.

Under the direct, or mechanical causes, may be discussed:—1. Too bulky meals. Too much food is taken at a single meal. This is not always because the individual is so very hungry, but because such a large variety of food is furnished for each meal, and the appetite is over-stimulated. At the same time, an excess of fluid is taken, adding greatly to the weight of the food ingested, as well as interfering with the process of digestion. 2. Rapid eating. or bolting of food. An individual who eats rapidly takes more food than is necessary, does not musticate it well, and uses an excessive amount of fluid, either water, milk, tea, coffee, or alcoholic drinks, to hasten the disposition of a meal. 3. Certain diseases of the stomach, such as chronic gastritis. In this condition, the food remains longer in the stomach than normal, fermentation takes place, gases are evolved, and the stomach is distended. 4. Abdominal tumours and pregnancy. These conditions distend the abdominal walls. When the tumour is removed, or after labour, the abdominal walls being relaxed, the stomach is not supported as before, and dilatation takes place. 5. Chronic constipation. The colon being heavy with large masses of fæces, considerable tension is brought upon the greater curvature of the stomach which tends to dilatation. 6. Constriction of waist by too tight, and suspension from waist of too heavy, clothing. Many women (and some men) wear tightly laced corsets, which are supposed to give the body a more natural and graceful shape. Thus the organs are pushed out of shape. The abdominal muscles are put in splints, so that from disuse they soon lose their tone and strength, and fail to afford the normal support to the stomach. The mischief done by the corset, and moderate lacing, however, is not nearly as great as that which results from suspending heavy clothing from a waist which has no support and stiffness. The constriction and weight of heavy skirts, worn over the ordinary corset waist.

(a) Abstract of paper read before the Ontario Co. Medical Society, Canandaigua, N.Y., January 10th, 1899.

produce a great amount of tension and dragging down upon the abdominal organs.

It is said by some writers that sometimes the small omentum is unusually short, and the pylorus holds a higher position relative to the fundus than normal. The increased resistance to the passage of food into the duodenum, thus produced, tends to dilate the stomach.

Under indirect, or nutritional, causes, may be considered:—1. Worry, anxiety, and overwork, either mental or physical. When food is taken under such mental or physical. When food is taken under such circumstances, digestion is often retarded, and sometimes entirely absent. Not only the secretory, but also the motor, function of the stomach is impaired, and the stomach becomes dilated. 2. Neurasthenia. There is scarcely any doubt that this neurosis is nearly always accompanied by faulty nutrition. The patient eats, but, under the severe nervous and mental strain, does not digest or assimilate sufficient nourishment to maintain normal strength or body weight. Worry is the initial cause more often than overwork. This impedes digestion and assimilation. The highly organised nervous system soon feels the lack of nutrition, and then the fatigue neurosis manifests itself, which again reacts upon nutrition, and thus a vicious circle is established. The nervous energies are remorselessly continued, and reserve strength is steadily expended. The patient says she is "living on her nerve." She would be nearer telling the truth if she were to say she is living upon the fat of her abdomen. The fat tissue which is so essential to support the organs and hold them in a position best suited to perform their functions is used up, and the organs begin to sag. The stomach, besides becoming dilated, is often associated with the other organs in a general enteroptosis. In a paper which I read before this Society a year ago, upon movable kidney, the subject of faulty nutrition was considered with some detail. 3. Certain diseases of the central nervous system, such as tabes, multiple sclerosis, &c. Atonic dilatation may follow as a result of febrile diseases, especially typhoid fever. Anæmia and chlorosis are mentioned by some writers as causes of atonic dilatation, while others speak of these blood conditions as the result of dilatation of the stomach. There is no doubt that these conditions are frequently associated, but their causal relation is rather uncertain. It would seem to me that their early association is a coincidence, but later in the course of each condition the other may occur in a secondary relation.

Dilatation of the stomach, when it is considered simply as a symptom, must be associated with the symptom group which reveals the underlying disease, before its diagnosis, or recognition, can be of any clinical value. To make a diagnosis which will be of any value therapeutically both the chemistry and motility of the stomach must be considered important factors. Not many years ago all study was directed to the chemistry of the gastric juice; later, the size and motility of the stomach have been receiving the most attention. Neither of these factors can be safely ignored.

The normal position of the stomach, as described by Luschka, is as follows:—"The pylorus lies in the angle between the right border of the xyphoid and right costal cartilages. The lower border lies well above the umbilicus, and the fundus lies beneath the base of the left lung, and is almost covered by its projecting margins." Deviation from the normal size and position can be readily detected by inflating the stomach through a tube with a rubber bulb. succussion splash also affords important information in reference to size and position, but more expressly in reference to the tone and power of the muscular walls. The use of the stomach tube is necessary to

obtain the information which the chemistry of the

gastric juice furnishes.

It is not within the scope of this article to refer intimately to diagnosis. In passing, it may be well to add that it is important to distinguish between gastroptosis and atonic dilatation. A knowledge of the exact position of the pylorus will enable one to differentiate between these two conditions. Gastroptosis is sometimes associated with dilatation.

The treatment of dilatation of the stomach may be divided into: (1) Hygienic, (2) Dietetic, (3) Physical, and (4) Therapeutic.

1. Hygienic. The rôle which tight and heavy clothing, suspended from the waist, plays in this condition has already been referred. All clothing condition has already been referred to. must be worn loose, and suspended from the shoulders. This cannot be accomplished by putting the abdomen and chest into splints (a corset) and then fastening the heavy skirts to the corset. Neither can it be accomplished by using the ordinary commercial corset waist, and having the tight belts of the skirt buttoned to it. This last contrivance is a snare and a delusion, and intended to relieve a woman's conscience rather than the abdominal organs from presusually, when asking one of these patients with dilated stomach in reference to the way she wears her clothing, or if she wears a corset, she will either say, "Yes, I wear a corset, but very loose," or, "No, I wear only a corset waist, and suspend my skirts from the hips."

After considerable study and experiment, I have found a plan which I can, unhesitatingly, recommend to these patients. I ask them to wear union undersuits; instead of a corset or a corset waist, I have them put on a waist fitted by a dressmaker, specially them put on a waist fitted by a dressmaker, specially instructed; this waist being so made that when a skirt is buttoned to it the weight is really thrown upon the shoulders. To accomplish this three points must be observed: First, the goods, which is usually white drilling, must be so cut that when the skirt is fastened to it the weight will be in the direction of the weave of the goods and not diagonal to it, as it is in the covert waist of the shops. Second, the waist is in the corset waist of the shops. Second, the waist must fit exactly to the shape of the body, with suffi-cient room for respiratory expansion. Third, the cient room for respiratory expansion. Third, the buttons for the attachment of the skirts must be so high that when the necessary weight is thrown upon them, they do not pull below the line of the smallest circumference of the patient's waist. To such a waist, both the petticoat and the dress skirt are buttoned. The belts must be comfortably loose. Over this waist, the ordinary dress waist, or a basque, is worn, loose, but neat, and not hooked to the skirt below. During cold weather, instead of adding an underskirt, knitted woollen tights of desirable weight should be worn. Such a combination will afford comfort, and, at the same time, permit the most fastidious to comply with the varying fashions. These patients frequently go to sanatoriums, where the life is such that tight dresses cannot be comfortably worn. They wear wrappers and spend much of their time lying down. Improvement, if not entire recovery, takes place, and they return home, where they again put on their unhygienic clothing, and in a short time relapse to their former miserable condition.

2. Dietetic. In dilatation of the stomach, one must contend with the unfortunate circumstance that the very organ which is needed most to hasten a recovery is seriously disabled. It is essential, if the patient is below her normal weight (and this is nearly always the case) that she should regain, or go above, her normal weight. The abdominal organs must be in part supported by the normal amount of fat which is found in the abdomen in health. I know of no one food which will restore this more readily than milk in definite quantities at regular intervals.

I am aware that a liquid diet in dilated stomach is

contrary to the teachings and writings of many for whose opinions I have the greatest respect. tell us "a modified dry diet, concentrated, with meals at long intervals, coarse vegetables, and, if necessary, nutrient enemata, so that the stomach may have very little weighty material, and have long periods of rest. I have never yet succeeded in getting these patients to gain in weight upon such a régime. If one adopts the dry diet, and also has the patient take as much water as one in health ought to take in a day, I daresay the weight of the food and water will be equal to the weight of the milk necessary for one day. But these patients need to take more fluid than a healthy individual, because they nearly all suffer from partial anuria, are constipated, and in a condition of autointoxication.

I have had very satisfactory results in many cases: by giving these patients two glasses of good, rich nilk, with two raw eggs at meals, say at 8 a.m., 1 p.m., and 6 p.m.; and two glasses of milk at 11 a.m., 4 p.m., and 9 p.m.; sometimes giving an additional glass at midnight, or early in the morning. After these meals and lunches, the patient is required to lie flat on the back, or on the right side, for a period of thirty to forty minutes. I do not see that there can be any danger of aggravating an existing dilatation when the patient follows this course, for the weight of the food is not exerted against the lower-curvature of the stomach, but against the posterior wall, which is well supported by the underlying tissues

With such a diet, the kidneys become very active, the bowels often become regular, and the patient gains in weight. When the patient regains the normal weight, a meal of solid food is allowed at I p.m., consisting of a mutton-chop, and zwiebach, with about four ounces of water, and for the four o'clock lunch are substituted about twelve ounces of water. The other meals and lunches remain the same. If, after a week of experience with the mid-day meal, the patient holds her weight, a meal of solid food is ordered for breakfast, much as the mid-day meal, with the addition of a well-cooked cereal, and to the dinner are added green vegetables and soft-boiled eggs. The patient is advised to eat butter freely. Thus, gradually, the patient is given three meals of solid food

What of the patients who cannot take milk or raw eggs? There are many who think they belong to this class, but it is surprising to see how few really suffer from such an anomaly. The usual opinion is that there is too much acid in the stomach and the milk is curdled. From a careful study of the chemistry of the gastric contents, and observations upon the effect of milk in a number of cases, I have found that patients with hyperacidity are more likely to take milk without discomfort than those who have an absence of acid. A most decided case of hyperchlorhydria took milk easily, while one of achylia gastrica could not take it at all. It is not well to continue one diet with these patients too long. After ten days or two weeks of milk and raw eggs, it is well to have the patient take plain water for ten or twelve hours, equal in amount to the milk which would have been taken during the same time. this, the milk is again resumed. All foods which are likely to cause fermentation must be avoided. Among these are potatoes, rice, and white bread. Raw fruit and an excess of sweets and fats must also be avoided.

3. Physical. Under this are included massage of the abdomen; certain exercises intended to develop the abdominal muscles; faradic electricity applied to the abdomen, and alternate hot and cold packs, or alternate hot and cold douches applied to the abdomen.

The application of electricity in these cases has

been a question upon which there has been a diversity of opinions. Physiologists have proved that it is impossible to cause a contraction of the muscles of the stomach by the external application of the electrodes of a faradic battery, but that if one electrode is applied intra-gastrically, and the other over the abdomen, the muscles can be contracted at will. This has led to the use of the intra-gastric electrode. the chief end of the application of electricity to the abdomen in these cases is to cause a momentary contraction of the muscles of the stomach, the intra-gastric electrode ought to be of the greatest value. But more than this can be accomplished with faradic electricity in these conditions. The tone and strength of the relaxed muscles of the abdominal walls can be increased, and I believe that the digestion and assimilation of food can be increased. Gynæcologists, especially those who employ electricity, claim that they can alter tissues in the pelvic organs by applying electricity, pericutaneously. If this is true, would it not seem reasonable that electricity, applied in the same way, would, at least, alter the delayed functional activities of the transfer and howeld? I have tional activity of the stomach and bowels? I have used faradic electricity pericutaneously, and have obtained very satisfactory results.

4. Therapeutic. There are several drugs which can be used to great advantage in the treatment of atonic dilatation. Among these, the tincture of nux vomica can safely be said to take first place. Strychnine may be equally effective. A combination of the sulphate of quinine and strychnine is often very good. If there is diminished HCl in the gastric juice, small and frequently repeated doses of HCl are beneficial after the meals of solid food. If there is an excess of HCl, a combination of sodium bicarbonate, calcined magnesia, and bismuth subnitrate can be administered to advantage. If the constipation is not relieved by the hygienic and dietetic measures, and by the massage, the electricity, and the physical exercises to which reference has been made, glycerine suppositories may be used. Fluid extract of cascara sagrada, with tincture of belladonna and glycerine, may be given in small doses, if the suppositories are not effective.

The prognosis in these cases is good if the physician can have full control of the patient. Often the symptoms will disappear long before the stomach resumes its normal size.

Transactions of Societies.

CLINICAL SOCIETY OF LONDON.

MEETING HELD FRIDAY, MAY 26TH, 1899.

Mr. Langton, President, in the Chair.

Mr. H. Betham Robinson described a case of

INTESTINAL OBSTRUCTION, CAUSED ADHERENT VERMIFORM APPENDIX FORMING A BAND ASSOCIATED WITH FŒTAL ARRANGEMENT OF THE PERITONEUM.

A female child, et. 7, was admitted into St. Thomas's Hospital in March, 1898, with a history of a week's constipation and occasional attacks of vomiting, now becoming constant and dark brown in colour. She had a pinched appearance; julse 110, respirations, 38 per minute, and temperature 96.8, but without any marked collapse. There was acute pain in the belly about the umbilicus. Her abdomen moved with respiration, and was not rigid. There was particularly dis-tension in the middle line above the umbili-cus, and coils of small bowel were distinctly defined. There was comparative dulness on the left side. Teere had been no rectal discharge and no lump was to be felt there. It was doubtful whether she had passed flatus for the last few days. The abdomen was opened

in the middle line, and a quantity of fluid with a few lymph coagula escaped. The small intestine was so extremely distended that exploration was impossible until the intestine was tapped, and three pints of fluid removed. In the right flank there was no colon, and on the left side the colon was absolutely collapsed, which condition was traced along the transverse colon. To the left of the mid-line above the umbilicus a mass was felt which proved, on examination, to be a loop of small intestine close to the excum strangulated under a band formed by the tip of the vermiform appendix being coherent to a caseous mesenteric gland. Beyond the obstruction the intestine was completely compressed, whereas the small intestine on the proximal compressed, whereas the small intestine on the proximal side was very dilated. The cæcum and the whole of the ascending colon retained their primitive peritoneal investment, so that they could, and had, passed freely over to the left side. The appendix was separated and the intestine released. The child's condition was so bad as to require infusion. She did not rally at all after the operation and died very shortly. At the autopsy it was found that not only were the ascending colon and cocum freely movable but the third part of the duodenum had a mesentery.

Dr. HAWKINS, of Reading, suggested that the adhesion of the appendix was due to a former appendicitis.

Mr. Robinson, in reply, said he could not agree with this as the specimen showed there was absolutely no indication of appendicitis, and, moreover, it was not necessary to seek for this as the presence of the caseous mesenteric gland was the undoubted factor in the adhesion of the appendix.

HÆMORRHAGIC ERYTHEMA WITH ERIGHT'S DISEASE.

Dr. Colcott Fox related the case and showed drawings of the case of a woman, æt. 61, who had suffered from bronchitis and acute nephritis probably supervening on old mischief. She left the infirmary but returned a fortnight later (January 5th) with injected and swollen fauces, some erythematous macules on the face, and a few petechiæ on the legs. On January 10th a generalised eruption made its appearance. It was of an erythematous macular type slightly raised with a tendency to rapid centrifrugal extension. The eruption varied in size from a pinpoint to a finger nail, but tended to become confluent, forming patches and sheets. The colour was a vivid red, ineffaceable by pressure. The smaller lesions were dotted with distinct hæmorrhagic punctæ, and the large older ones acquired a welldefined purple border enclosing bluish red centres. palms and soles were diffusely involved but the fingers and dorsal surfaces were at first unaffected. The skin of the fingers, wrists, tots, and feet was edematous. The joints of the wrists and hands were tender and painful. By January 12th the eruption had become almost universal and looked at first glance like severe purpura. Over the abdomen the maculæ were mostly small and erythematous, and not nearly as hæmorrhagic as elsewhere. The face was sallow and the forehead covered with a morbilliform eruption. The lips were swollen and blood stained, and there were a few purpuric spots on the gums and palate. After a brief pause the lesions became increasingly hæmorbesing the statement of the sta rhagic and even more confluent. On the 15th recent retinal hæmorrhage was detected. On the 16th melæna occurred, and the patient died on the 17th. Before death the hæmorrhage was still increasing in the skin. Post-mortem a good deal of congestion of the lungs was seen, with intense injection of the mucous membrane of the trachea, bronchi, stomach, colon, and especially of the jejunum and ileum, where it was hæmorrhagic, There was no endocarditis. The kidneys were small, red, granular with a narrow cortex and adherent capsule. Microscopical examination of the affected portions of skin revealed distension of the lymph spaces and the blood vessels of the papillary layer with a moderate cell infiltration. The sheaths of the larger horizontal vessels were, however, densely infiltrated with cells. There was apparently no plugging of the vessels and no micro-organisms were discovered. Dr. Fox observed that the eruption appeared to correspond clinically with the roseola of Willan rather than with erythema multiforme.

He observed that one was familiar with cutsneous hæmorrhage as a complication of or even in lieu of the characteristic eruption of infective diseases such as variola and measles, and it was equally recognised that in erythema multiforme there was a special tendency to the exudation of blood-stained fluid, and even blood itself, which may completely mask the essential eruption. Hæmorrhage into the slighter roseolar forms of eruption was, however, rare. He added that in his experience the appearance of this kind of eruption in patients suffering from Bright's disease usually heralded approaching dissolution. They had been of two types—either the roseolar type of Willan, or of the morbilliform type. He mentioned the case of a woman who, two or three days before her death from granular kidney, became covered with a copious eruption of dusky erythematous macules the size of the finger nail, closely simulating the roseolar syphilide. He had also seen several examples of a copious generalised mor-

billiform eruption, terminating in profuse desquamation.

The President observed that the case would be a valuable supplement to those brought before the Society

not long since by Dr. West.

AMEURYSM OF THE SUBCLAVIAN ARTERY TREATED BY LIGATURE OF THE FIRST PORTION, FOLLOWED IN THIRTY-EIGHT DAYS BY BEMOVAL OF THE ANEURYSM.

Mr. H. Allingham showed a man, æt. 25, a sailor, admitted February 20th, 1899, who three years before had noticed a swelling above the right clavicle which had gradually increased in size, especially during the twelve months preceding admission. On admission he exhibited a pulsatile expansile swelling in the right supraclavicular region between the sterno-mastoid and trapezius muscles, about the size of a tangerine orange. There was characteristic systolic bruit with delay and diminution of the right radial pulse. He ligatured the subclavian artery on the cardiac side of the tumour, using a kangaroo tendon ligature immediately external using a kangaroo tendon ligature immediately external to the origin of the vertebral artery. Recovery was complete, no pulsation being perceptible in the tnmour or in the radial artery until March 4th, when some slight beating was detected in the aneurysm. This continued, and the sac became distinctly smaller and harder. The patient was anæsthetised whan it was found that the tumour, although pulsating, did not expand, and it was decided to watch the case for a time before proceeding to more radical measures. On March 28th it was noted that the aneurysm was increasing in an upward direction, and that there was increasing in an upward direction, and that there was decided palpable and visible pulsation. On April 8th the whole length of the clavicle was exposed and the greater part removed. The aneurism was carefully exposed, springing from the upper and anterior aspect of the vessel. Silk ligatures were applied above and below and the sac removed. During the dissection the transversalis colli artery was wounded as it crossed the tumour, and some few fibres of the brachial plexus were divided, the lower cord of which was adherent to the sac above. Some difficulty was experienced in separating the subclavian vein, which received a slight tear, which was closed by a lateral ligature. The patient rapidly recovered, and was now about, using his right arm with comfort. Section of the aneurysm showed that its cavity was largely occupied by firm clot, the blood passing into it from the subclavian and out posteriorly by what appeared to be the profunda cervicis. A careful examination of the arm was made on May 5th, and it was found that pulsation was present in the brachial, best marked in the ante-cubital space, and also in the radial at the wrist. The ulnar was not felt. The hand and fingers were pallid, and somewhat colder than those of the opposite limb, but this condition was improving daily. He remarked that little or no difficulty was experienced in applying the ligature to the first roution of the subelevien extern set it was the first portion of the subclavian artery as it was approached from below, and the dissection was made from the region of the second portion, thus the large veins and nerves crossing the seat of ligature were not even recognised.

Mr. STANLEY BOYD observed that these cases were so rarely successful that the author deserved to be con-

gratulated. He had been struck by the fact that the pulsation had returned very soon after ligature of the first part of the artery. That appeared to be common after proximal ligature for aneurysm of the third part of the subclavian, and constituted a strong argument in favour of excising the sac. With free exposure of the aneurysm it ought not to be more difficult to put a ligature round the artery at the start than later, and that had, indeed, been done on at least three occasions. He said the result in this instance after complete removal was interesting, and it would be interesting to note whether the shoulder dropped in the future more than it did at present. In fact, at present there was no drooping to speak of. Another interesting point of view was the reason why hemorrhage was so very common after ligature of the first part of the subclavian. The subclavian had been stated to be the thinnest artery in the body, and in any case one of the great difficulties was to arrange the artery comfortably after ligature, as there was always such a large gap left.

Sir Dyce Duckworth mentioned the case of a patient under his care with aneurysm of the subclavian. He had placed him on a restricted diet, giving large doses of iodide of potassium. Mr. Howard Marsh had seen the patient, and was of opinion that it would be a very suitable case for this operation; but, inasmuch as the aneurysm was becoming smaller and was consolidating,

it was decided not to interfere for the present. Mr. CHARTERS SYMONS related a case of aneurism of Mr. CHARTERS SYMONS related a case of aneurism of the second portion of the subclavian in which he had attempted to ligature the first part. It was situated underneath the clavicle, but the whole posterior triangle was filled with a pulsating swelling which extended to the sterno-mastoid. He proceeded to apply a ligature to the first part on the plan suggested by Ballance and Edmunds. On exposing the artery by splitting the sterno-mastoid, and on cleaning it, on passing a needle from below there was a furious rush of blood which from below there was a furious rush of blood which ceased on his withdrawing the needle. On reintroducing the needle the rush of blood recurred. He therefore tied the innominate and common carotid on that side at the same time, and so far the case had done well. The curious thing happened that the whole of the sac separated, but the patient recovered with a fairly useful arm. He asked whether the author had divided the head of the sterno-mastoid muscle.

The President thought the fact that the author had used kangaroo tendon for the first ligature and silk for the second, was rather ominious. He had never himself ligatured the first part of the subclavian for aneurysm, but he had had two examples of malignant disease of the clavicle in the centre, and he had removed almost the entire length of the bone. In both cases a very good result had followed with no impairment in either of the limbs. If, therefore, it was thought desirable to remove that bone, it might be done without hesitation.

Mr. H. Allingham, in reply, said that he had freely divided the sterno-mastoid an inch above the clavicle, afterwards uniting it by sutures. By so doing, the inner border of the scalenus anticus was easily exposed and there the artery was found pulsating, and a ligature could readily be passed round it. He had used kangaroo tendon for the first ligature in deference to the advice of his colleagues, but on the second occasion he had preferred to the light of the state of the second could be set in was what he was in the light. sterilised silk as this was what he was in the habit of using. Before the operation he had tried to find out what would be the result of removing the bone, but had not been able to get any information on the subject.

The business of the Annual General Meeting was then

proceeded with.

ROYAL ACADEMY OF MEDICINE IN IBELAND SECTION OF OBSTETRICS.

MEETING HELD FRIDAY, APRIL 21st, 1899. The President, Dr. F. W. Kidd, in the Chair.

TWO YEARS' WORK AT THE SAMABITAN HOSPITAL FOR WOMEN, BELFAST.

Dr. John Campbell gave an account of two years' work at the Samaritan Hospital for Women at Belfast.

The hospital contains thirty beds, as well as nurses' apartments. Of these, eight are in the isolation wing and are devoted to the treatment of cancer and septic cases. Patients about to undergo an operation are well scrubbed with soap and water, and wear boric compresses over the seat of operation for three or four days beforehand The day before operation the field is well washed with soap and water, rubbed with turpentine, again washed with soap and water, and finally washed with 1 in 1,000 sublimate solution, and covered by a compress wrung out of the same. This preparation is repeated on the morning of the operation day. Septic cases are, as far as possible, excluded from the operation room. Sterilisation by boiling is carried out in regard to everything to which it can be applied. The hands are cleansed by thorough washing, followed by washing in turpentine, and again in soap and water. They are then put through the permanganate and sublimate processes in succession. India-rubber gloves are used if a septic case has been recently handled. The gloves are boiled. Chloroform is given by Junker's inhaler. Sickness Chloroform is given by Junker's innater. Sickness in a patient is regarded as indicative of returning consciousness and of incompetence on the part of the anæsthetist. By the sponge and towel methods the patient is alternately half-poisoned and half-conscious. Flushing the abdomen is done in tuberculous peritonitis and cases in which glairy fluid has escaped into the abdomen. Drainage is used after flushing, in cases where much peritoned fluid has been present and in cases in much peritoneal fluid has been present, and in cases in which pus has escaped. The current of opinion has now set in too strongly against drainage. A glass tube with a gauze wick is to be preferred, and the bed-head should be raised. Small gauze drains float on the intestines. Large ones prevent the bowels from resuming their natural position. A rigid tube keeps the gauze in the pelvis. Dressings: Sterilised gauze is used for most cases. Iodoform is used for wounds which are drained. Post-operative Treatment: Morphia is, if possible, avoided. One half grain hypodermic may be given if pain is severe. The amount of fluid allowed depends on the amount of vomiting present. During 1897-98 fortyfour intraperitoneal operations were performed in the Samaritan Hospital by Dr. John Campbell, namely:

1. Twenty ovarian tumours, including sixteen ordinary
cysts, three dermoids, and one solid tumour. The
patients' ages varied from 21 to 65. In three cases both ovaries were removed; in four one ovary was removed and the other resected. In one case a fæcal fistula was present for a fortnight, and in one phlebitis occurred in the left leg after puncture of small cysts in the corresponding ovary. All the patients recovered. 2. Diseases of the tubes were operated on in three cases. In one the tubes were catheterised; in another a four months' feetus was removed from the right broad ligament; and in one a tumour of myomatous appearance was removed from the inner end of a tube, the outer end of which was dilated and contained fluid like menstrual blood. 3. A fibro-cystic tumour independent of the tube and ovary, and not obviously connected with the uterus, was removed from the right broad ligament. It weighed 20 lbs. 4. Fibro-myomata of the uterus were operated on nine times. Four were abdominal operations, done by the intraperitoneal method; two were vaginal hysterectomies; one was an enucleation after abdominal section; and one was an exploratory incision, in which the appendages could not be got out, and the patient could not stand panhysterectomy. The enucleation case died of shock; the others all recovered. 5. One case of cancer of the corpus and one of cancer of the cervix uteri was successfully removed by vaginal hysterectomy. 6. A case of prolapse and one of retroversion were treated by vagino-fixation, with good result in both cases. 7. Tuberculous peritonitis was incised and drained twice. The case in which there was much fluid appears to be cured; the other was not benefited. 8. A hydronephrotic kidney and a tuberculous kidney containing abscesses were removed with success. 9. Gastrostomy for cancer of the œsophagus was done once with excellent result. The vermiform appendix was once removed. A cancerous excum was exposed with the view of making a feecal fistula and excising the growth when the patient had recovered from the effects of the

intestinal obstruction caused by the growth, but she died exhausted after the preliminary operation. The mortality of these forty-four cases was 41 per cent., as good an average as can be expected, if operations on so many different abdominal organs are taken together.

The President thought that gloves should be used in operations only when they suspected that they could not render their hands completely aseptic. He did not agree with Dr. Campbell's opinion that all the dangers of chloroform were due to maladministration. When chloroform was administered guttatim he had seen no ill effects

Dr. Smith said he had practically given up drainage. He believed that after a few hours no drainage took place, since a layer of protective lymph was thrown out round the tube which acted as a foreign body. Moreover, a solid drainage tube pressing against the rectum was capable of causing a fistula. The operation he was capable of causing a fistula. The operation he preferred was retro-peritoneal hysterectomy, which gave excellent results.

Mr. M'Ardle observed that nearly all the abdominal viscera reflected pain to the pelvis after laparotomy. It was not uncommon in gouty affections of the kidneys to have the pain referred to the pelvic region, and in many instances of spinal lesions the chief pains were pelvic. He strongly advocated the intraperitoneal method of operating, and considered drainage of the peritoneal cavity unnecessary, except where there was some intes-

Dr. Purestor said he was one of those who practised drainage, but he had never used a rigid tube. The gauze drain, in the form of a Mikulicz' bag, or otherwise, he was satisfied was of the utmost use.

Dr. CAMPBELL, replying, said he believed that sudden death during the administration of chloroform was generally due to the use of a too concentrated solution. With regard to drainage, it was quite true that it was useless after a few hours, but it was during those few hours that it was especially required. He considered the vaginal method of operating on fibroids the best, when it could be done.

ON UTERINE CANCER AND ITS TREATMENT. Dr. More Madden read a paper on this subject which

is published in abstract elsewhere.
The President said there were many conditions which resembled the initial stage of uterine carcinoma. A microscopic examination was therefore always desirable. He had performed vaginal hysterectomy on seven patients for malignant disease. Four of them, at least, he knew to be still alive.

Mr. M'ARDLE said with reference to removal of the glands with the uterus and appendages, he had never yet seen thorough removal of the retro-peritoneal glands. In operations for tuberculous disease of the vermiform appendix it was his custom to rip up the peritoneum

and remove the glands involved.

Dr. Smith said sufficient stress was not laid upon rectal examination for the purpose of determining infiltration of the surrounding tissues. He thought that the best chance for the patient was offered by the abdominal method of operating if there was any doubt about the case.

Dr. Purefox said that when he recognised malignant disease in the uterus his inclination was to remove the whole organ.

The Section then adjourned.

HARVEIAN SOCIETY OF LONDON. MEETING HELD THURSDAY, MAY 18TH, 1899.

H. E. JULEE, F.R.C.S., President, in the Chair.

CONSIDERATIONS AS TO THE ETIOLOGY AND SIGNIFICANCE OF DILATED HEART.

DR H. A. CALEY read a paper with this title, a full abstract whereof will be found elsewhere.

Dr. ALEXANDER MORISON considered that the simplest method of regarding the etiological factors in the production of cardiac dilatation was to remember the essential triunity of the so-called functional unit, and to

refrain from dissociating the muscular, hæmic, and neural elements of which it was composed. He protested against the tendency of many physiologists of the present day in regarding the muscular element as the predominant factor in sustained rhythmical action, and considered that both clinical experience and pathological investigation, rudimentary though the latter still was, pointed to the important $r\hat{o}le$ played by the nervous system in such cases.

Dr. John Broadbent said that the question as to what were the factors which determined the relative amount of dilatation and hypertrophy after endocarditis, was one of great importance. He considered that the myocarditis which so frequently accompanied endocarditis and not the actual lesion to the valves, was responsible for the initial dilatation, from which the heart might entirely or only partially recover. Subsequently, as the valves became puckered and defermed in the process of repair by cicatricial contraction of the granulation tissue on their surface, the effects of valvular lesion became pronounced, and led to fresh dilatation of the heart followed by hypertrophy, which constituted a measure for estimating the extent of the valvular lesion. It was important, therefore, not only to enjoin absolute rest after an attack of endocarditis during the period when the heart was recovering from the initial dilatation due to accompanying myocarditis, but subsequently to insist on great care and moderation in exercise at a later period when the compensatory changes called forth by the valvular lesion, were taking place. Otherwise undue permanent dilatation with excessive hypertrophy might ensue.

Dr. G. A. Sutherland asked whether dilatation was ever present without hypertrophy. Dilatation must be either an active or a passive process as regards the cardiac muscle. A passive dilatation or cardiac failure implied that the blood could be pumped through the arterial and venous systems by the left ventricle in a weakened condition, and yet remain under sufficient pressure to dilate the ventricle. It was difficult to accept such an explanation on physical grounds, as venous engorgement and cardiac syncope would appear to be a more likely result. Active dilatation, on the other hand, might be the calling into play of some reserve power in the heart, which by greater expansion and more rapid action was enabled to carry on the circulation. As compensation was often fully established under these conditions, he thought that dilatation might be looked on as a conservative process, and one not necessarily to be interfered with medicinally or otherwise, although it was recognised that over-action of the heart was present, and that a breakdown must

occur in the course of time.

Dr. POYNTON agreed with Dr. Sutherland as to the difficulty in many cases of explaining dilatation of the heart upon mechanical considerations. In rheumatism dilataupon mechanical considerations. tion might be very marked, and the clinical symptoms comparatively slight, whereas in other conditions the clinical symptoms might be very severe and the dilatation slight. Microscopic examination of the heart walls sometimes showed extensive myocardial disease with little dilatation, and sometimes the reverse. In rheumatism he thought it probable, a view also held by Dr. Lees, that the marked dilatation was dependent upon a special and peculiar action of the rheumatic toxin upon the cardiac muscle. The difficulty and complexity of the question of cardiac dilatation was illustrated by the case of a young man about twenty-four years of age, who having been "out of sorts" for some days went for the first row of the season in a "four oar" to "shake it off." On landing after the exertion he vomited, and later in the day was seen by a doctor, who found that his heart was extremely rapid, his pulse rate being about 200 to the minute. He was admitted under Dr. Cheadle, to St. Mary's Hospital in this condition, and died two or three days afterwards, the heart acting to the end at this extraordinary rate. The post-mortem showed some mitral valvulitis and old pericarditis. The dilatation was quite moderate. In this case there were two factors, a damaged heart and a mechanical strain, both, one would have thought, leading to extreme dilatation rather than a condition of tachycardia with little dilata-

tion. He thought it was important to get a definite idea of the meaning of fibrous changes in the heartwall, for sometimes they were brought forward to account for dilatation, and sometimes they were given as an explanation of its absence. These fibrous changes, which arise in connection with the vessels, were, he thought, essentially reparative, and an evidence of Nature's reaction, however imperfect, to morbid processes. The valve deformities in rheumatism were thus an evidence of reaction to the toxic process, rather than an evidence of the active effects of the toxemia. He thanked the Society for their permission to show the microscopic specimens.

Dr. Bezly Thorne was glad to find so much importance attached to the first stages of dilatation, because by their early recognition and relief the physiological call for hypertrophy and the ultimate sequelæ of de-generation and loss of compensation could, in a large number of cases, be obviated. With regard to tobacco poisoning, the practice of inhalation was the most certain and rapid in evil effect. Abnormal sexual ex-With regard to tobacco cesses were the cause of cardiac dilatation in other cases, and some of those the most obstinate. He added that myocardial and vascular degenerations which had not proceeded to calcification, and especially those which were attributable to atheroma and fatty degeneration were among the most amenable to treatment of cardio-vascular affections The free ingestion of water, at such times as not to interfere with gastric digestion, by promoting elimination of toxins, was an effectual means of reducing vascular tension in cases in which sclerotic changes had not rendered increase of arteriallumen impossible, not excepting cases of commencing dilatation of the aorta.

Dr. H. A. Caley, in reply, remarked that practically we could only estimate alterations in the cardiac nervous mechanism by noting any alterations in the frequency, or by those of the heart test, and by restricting, as far as possible, the amount of contractile vigour which the heart muscles possessed. In reply to the question as to whether slight degrees of dilatation might not be beneficial it was pointed out that just as a slight degree of dilatation under physiological conditions might be a mechanical advantage, so a corresponding degree of dilatation under pathological conditions might likewise be advantageous, provided that it was accompanied by sufficient vigour of the heart muscles, with or without actual hypertrophy. This had been referred to in the

paper as strictly compensatory dilatation.

Dr. Poynton exhibited microscopic specimens illustrating various diseased conditions of the myocardium. The sections were taken through the left ventricle papillary muscles, and in one case the aorta. They showed the general fatty changes that may occur in severe rheumatic morbus-cordis, the extreme myocardial disease that may occur in some cases of alcoholism, and the severe and active changes that may be found in the heart wall in acute aortitis, without demonstrable affection of the coronary vessels. The explanation of the condition in these cases of aortitis was in all probability that a process analogous to that in the aorta had taken place in the heart wall itself.

SECTION OF THE SYMPATHETIC.

At the last meeting of the Académie de Médecine M. Franck spoke on his experiments on the section of the sympathetic nerve in the treatment of Basedow's disease, and the effect produced on the circulation of the thyroid body on that of the brain, the ocular apparatus, and upon the head. The cervical cord of the sympathetic acts as the nerve of propulsion of the globe of the eye, thanks to its action on Müller's muscle; its section suppresses or attenuates exophthalmis. On the other hand thi

nerve acted simultaneously as constrictor and dilator of the vessels; its section diminishes the tension intra-oculaire and can consequently have a beneficial influence on glaucoma. As to the supposed vaso-dilating action of the cervical sympathetic on the thyroid gland it did not exist. Irritation of this nerve determines, on the contrary, contraction of the thyroid vessels, and its section consequently cannot do otherwise than add a paralytic vaso-dilatation to the active congestion of exophthalmic goitre.

The vaso-constrictive cerebral action of the sympathetic is none the less apparent; it is thus that section of the cervical cord increases the cerebral blood current. The profit that could be derived from its section for Basedow's malady and for epilepsy was problematic, the theory of cerebral ansemia in these two affections being very questionable.

The cardiac nerves derived from the sympathetic are only furnished in a small proportion by the cervical cord, they derive for the most part from the superior thoracic region. Their suppression is consequently only complete in the case of total resection. Irritation of the aortic and cardiac branches, like that of the sympathetic, are capable of provoking a series of troubles in the circulation similar to the accidents of Basedow's malady.

TREATMENT OF URAMIA BY WATER DIET.

M. Renon said that there were cases of acute or chronic uræmia where the patients could not support the milk diet; the accidents persist, in spite of the milk, and perhaps even on account of the milk, which becomes a poison, as in cases of acute enterocolitis, and probably for the same reasons. In such cases, consequently, some other agent than milk should be employed. M. Mathieu showed that in the course of chronic gastric urmmia the patients could be treated simply with water, and he knew that M. Bar treated for the last year by the hydric diet, and with good results, women suffering from gravid albuminuria and from eclampsia. He thought, consequently, that in uramic patients who did not support the milk the hydric diet should be observed. In five cases he prescribed this treatment. At the end of three or four days the vomiting, diarrhea, and dyspnea had disappeared, and the days following rice-water and vegetable soup were ordered, and gradually the milk diet was resumed.

THE ACTION OF COLOUBED LIGHT ON MAN.

Dr. Raffegean has published an interesting account of his treatment of nervous affections by coloured light. In a room papered in red and with red glass windows he placed a maniac, who, for a long time, was sombre, affected with taciturn delirium, and ate rarely of his own accord. Three hours after being placed in this room he visited him, and to his great surprise he found him smiling all over, and asked to be given something to eat.

Another patient took it into his head that the air was full of poison, and remained all day with his hands over his mouth to prevent the air from entering. He was placed in the red room, and the following day he seemed quite rational, asked for his breakfast, which he swalowed with avidity, and at the end of a few days he was able to be sent home. On the other hand, a maniac, very violent, and wearing the straight jacket, was put into a room with blue glass windows, and in a few hours he became calm and gave no further trouble.

M. Lumière, the well-known dry-plate manufacturer at Lyons, was obliged to substitute green coloured glass

in all the windows of his large room for the usual red, as the work people sang all day, gesticulated, and the men made love to the women. Since the substitution they are quiet, do not speak a word, and seem less fatigued when they leave off work.

Germany.

[FROM OUR OWN CORRESPONDENT.]

BERLIN, May 27th, 1899.

TRANSPLANTATION OF CARTILAGE INTO THE LARYNX. At the Surgical Congress Dr. von Branegoldt, Dresden, gave a note on the subject in connection with some cases of stenosis of the larynx. In some cases of stricture dilatation did not always lead to recovery, and scarcely to improvement. In such cases success could only be attained by resection and the implantation of fresh firm tissues into the stricture. The transplantation of hyaline cartilage had not, up to now, been attempted, but he had practised it in four cases with success, where there was defect of cartilage. In one case, that of a child, there was extensive papillomatous growth on both vocal cords. Laryngofissure was performed, the papillomata removed, and the surface cauterised. After five or six weeks stenosis was apparent, which could not be overcome by dilatations, nor could it be kept from getting worse. It was not possible to implant soft tissue, as on inspiration it would have been drawn in like a flap. He then attempted to implant rib cartilage with the perichondrium. cartilage was first of all implanted into the skin. and then the skin, made firm by the cartilage into the larynx. Intubation was also performed. The success was complete. The patient breathed and spoke well. He had endeavoured to discover whether the cartilage remained alive or not after the implantation. Some weeks ago he implanted some cartilage from a rabbit under the skin of the back, and showed in a microscopic specimen young vessels passing into the cartilage, a proof that it remained alive.

Hr. Krettner, Tübingen, read a note on THE EXTENSION AND PROGNOSIS OF CANCER OF THE PRNIS.

In two cases of cancer of the penis he found, contrary to his expectation, disease in the pelvic glands, while the inguinal glands were free. In order to come to an understanding of this striking fact, he made a series of injections of the lymph vessels of the neighbourhood, and found two groups, a superficial and a deeper. The superficial lymph vessels led to the inguinal glands, the deeper, almost without exception, direct into those of the pelvic. In amputation of the penis extirpation of the inguinal glands blocked the way for the spread of the disease. This was only in the early stages. Wherefore operation should not be delayed when cancer attacked that organ.

Hr. Most, Breslau, read a paper on the
Lymph Vessels of the Stomach and their Relation
to the Extension of Cancer,

and showed preparations and drawings illustrative of the subject.

Hr. Kraske, Freiburg, said that a few weeks ago a patient came under his treatment who had long been treated for ulcer of the stomach, but now showed symptoms of disease of the bowels. A high-

seated tumour could be felt from the rectum. Operation was performed, and the tumour removed from the sigmoid flexure, along with the bowel implicated. The extirpated piece showed an unusual appearance. There were two separate patches of the disease inside, not raised, but sunk and ulcerated, and a doubt arose as to whether the disease was carcinoma or not. Five days after the operation vomiting and pain came on, and three days later death. The autopsy revealed still further stenoses of the same kind both in the small and large intestine and also in the stomach. In the bowel the carcinoma lay especially below the mucous membrane. The disease of the stomach was the primary, the other secondary. The disease passed first into the left gastroepiploic artery, which also passed to the right and there united with the gastro-duodenal. The superior pancreatico-duodenal was a lateral branch of this, which encircled the head of the pancreas and supplied the greater part of the duodenum. The organ was again connected with the inferior pancreatico duodenal, this was the inferior mesenteric, which divided into two branches, the left colic which supplied the descending colon, the superior hæmorrhoidal which passed to the upper and middle part of the rectum.

CLINICAL CONTRIBUTIONS TO PERITYPHLITIS.

Hr. Karewski remarked on the importance of accurate differential diagnosis. It appeared that when bladder symptoms were present the prognosis was better. On the other hand attacks not preceded by peritonitic symptoms gave a worse prognosis, as here the abdominal cavity was a virgin one that reacted more readily on interference, with peritonitis. Retro-peritoneal suppurations were common, but they were, as a rule, of benign nature, but they could sometimes be malignant when they were only partially extra-peritoneal.

Hr. Gussenbauer, Vienna, said that vague pains often depended on adhesions which might be spread over a large part of the abdomen. If these were relieved the pains generally disappeared.

Hr. Kümmel, Hamburgh, would not operate in mild cases; in medium cases only when serious attacks came on; in diffuse peritonitis at once and without loss of time. Out of 850 cases he had operated in 57 with 32 deaths; out of the remainder there were only 11 deaths. The pulse always gave the clue as to whether a case should be operated on or not. Rehn had operated 19 times in diffuse peritonitis, nine of the patients recovering. Hr. Ewald, Berlin, also depended more on the pulse than on the temperature.

Hr. Körte, Berlin, said his standpoint was that generally the appendix was not to be resected, and in any case a free interval should be waited for. As a rule, simple opening of the abscess was enough. It should not be forgotten that 90 per cent. of appendix cases got well with internal treatment. Statistics proved that.

Hr. Jordan, Heidelburg, related a case of acute peritonitis that got well without operation. There was high fever, pulse 140, vomiting, collapse. Operation was declined. He heard nothing more for six weeks, when the patient was brought to him suffering from chronic peritonitis. After watching the case for a week an incision was made, and a large quantity of purulent material removed. Complete recovery took place.

VIENNA, May 27th, 1899.

RONTGEN RAYS AND SYCOSIF.

At the Gesellschaft der Aerzte, Shiff, in conjunctionwith Freund, gave their experience of the Röntgen rayson sycosis and favus. In both diseases when the rayswere applied seven and thirteen times respectively complete recovery was obtained, leaving the skin free from all inflammatory contractions and smooth. The action of the rays seem to be antiparasitic as no recurrence hadappeared after the second month.

Herpes tonsurans was equally amenable to the rays.

RUPTURE OF GALL BLADDER.

Hochenegg showed a woman, æt. 47, on whom he had operated for presumptive volvulus. history began with an illness that seems to have been intermittent in its character, with violent pains in the abdomen, accompanied by vomiting. This went on for some time, till a sudden tear, as if something had given way in the abdomen, occurred, and a large tumour formed which necessitated immediate action. No gas or fæces came from the bowel, neither was there vomiting or hiccough present after this occurrence. On opening the abdomen it was found filled with gall-coloured fluid, and six litres being drawn off. Further exploration. revealed the gall bladder torn and collapsed, and remained a large stone. After removing the stone and washing out the abdominal cavity the gall-bladder was stitched and the wound closed, after which the patient steadily returned her usual health, as might be seen from her present condition thirty days after operation. Owing to the wide diffusion of fluid in the peritoneal cavity, a drainage tube was left in the wound to prevent imbibition if possible.

Hochgnegg remarked that this condition of stone in the gall-bladder was not an uncommon occurrence, as 1,700 such cases were now recorded, 472 of which had been laparotomised, as no other form of treatment was rational under such circumstances.

Fabricius said that he had had three similar cases under his care some time ago which had been allowed to proceed further than Hochenegg's cases. The first was diagnosed as a case of hernia at the umbilicus which was treated till it burst and discharged a large quantity of purulent matter. On examining the opening a few gall stones were discovered embedded under the skin around the orifice. The second case had a similar history and was diagnosed as a fibroma, being located about the same place. The third was somewhat different but formed a large abscess in the sheath of the rectusmuscle the discharge containing the gall stones.

CHRONIC CAVERNITIS.

Grünfeld presented a patient with a chronic swelling about 5 c.m. wide and 6 c.m. long on the corpus of the penis entirely destroying the function of the organ. There was no pain with the swelling, which for some time has been considered malignant, though no confirmation of this could be adduced beyond swelling of the left inguinal glands. In malignant cases the Röntgen rays reveal a sort of cartilaginous substance which, strange to say, is present in this case. The microscope and symptoms were against, while the size of the glands and the Röntgen rays appearances were in favour of malignancy.

MYOMA OPERATIONS.

Wertheim next read his paper on 53 operations for myoma which he has performed during the last year and a half. Since Chrobak promulgated his methods of vaginal and "morcellement," five years ago for the removal of myoma, Grünfeld tells us that he has devoted most of his time to testing the different forms, and within the last year and a half has had 53 of this nature. He claims several modifications which are of considerable advantage.

His conclusions are that no tumour should be removed by this method if it rise above the umbilicus, as the loss of blood is too great to justify the operation. The length of time the patient has to be under chroloform is another danger to be feared. If the tumour be pediculated, it should be ligatured, and the stump returned to the uterus. In the case of multiple myoma the uterus must be removed with the tumor. The vaginal operation is limited in another class of cases; if these be anæmic or affected with myo-degeneration, even when tumour is small, this method should not be practised, as the hæmorrhage is apt to be so great as to precipitate a fatal result. Intra-ligamentary myoma, as well as the adhesive inflammatory form, should be removed by laparotomy. He has operated 36 times by the vagina, but in two intra-ligamentary cases had to abandon this method and complete the removal by laparotomy, 25 times "morcellement"—six times dismembering and three times enucleation. Of the 36 operations, one died of mvo-degeneratio cordis.

The radical cure he favoured was by total extirpation and supravaginal amputation, where there was less danger of wounding the ureters, and by removing the organ of the menstruating membrane danger was also removed, as well as fear of carcinoma in stum p.

The indications for total extirpation were:—(1) Colloid myoma, which developed in the pouch of Douglas; (2) very large, or multiple myomata, though small; (3) infection or complication with pus discharges.

Of seventeen radical operations he performed, three were supravaginal and fourteen total extirpation, with only one death.

Cape Town, May 10th.

ILLEGAL PRACTICE AT THE CAPE.

A good deal of interest has been excited locally over the prosecution by the police of an American negro. named Henry Tate, for illegally practising medicine at Claremont, a suburb of Cape Town. The accused claimed to be a graduate of the Western Reserve University Medical College of Cleveland, Ohio, and had applied for registration here, but had been refused, the diploma not satisfying the requirements of the Cape Medical Council. From evidence it was abundantly proved that the defendant had been carrying on an extensive practice, both prescribing and dispensing, under the guise of a semi-religious institution, the patients paying 2s. 6d. per week during illness, soul therapeutics being apparently included. To make matters safe, 10s. was always paid in advance as an entrance fee. He admitted having attended 800 patients in two years. The serious feature in the business is the implication of a duly

registered practitioner, Dr. Anthony, a graduate of Michigan and superintendent of the Claremont Sanatorium, a large institution carried on by the Seventh-Day Adventists, which, with ethical ideas truly Transatlantic, has extensively advertised itself and its doctor. For this reason, and from its tendency to subordinate true therapeutical lines to religious and vegetarian fads, it has never been in good odour with the local profession. Dr. Anthony was alleged by severalwitnesses to have personally assisted Tate, under the name of "Dr. Green," and although this was denied by the defendant, who stated that the mysterious "Dr. Green" was really Dr. Anthony's son, it was admitted that Dr. Anthony had given death certificates to cover Tate, and that without seeing the patients. Anthony had, in February last, written to Tate declining to continue this dubious practice, as it was a violation of the laws of the land, but naïvely admitting that, if his time had permitted his seeing the patients with Tate "once or twice," he could have gone on doing so. Eventually Tate was fined £50, with the alternative of six months' imprisonment, but appealed, and was allowed out on bail. It may be well to point out that the colonial law is in advance of that of England by making the unqualified practice of medicine penal, apart altogether from professing to be registered. This renders prosecutions fairly easy, and, as a matter of fact, there is very little quackery in this colony, although it is rampant in the Republics. The only defence made in this case was that Tate was not practising for gain; but for religious purposes. A certificate he gave for the removalof a patient to hospital is a gem, and I reproduce itverbatim:-

"This is to certify that I have been the attending physician of Mr. Charles Fredericks, age 62, from January 7th, 1899, and I find no contagious disease or Faberish disease. But owing to his age and the location of his residence, his complaint has been of such Nature and now, and there is nothing more can be applied to his life sustenance. Only a quiet nursing, as he is now on his margins to his long home. God help him. There is quick rattling over his bones. Given under my hand this 17th day of March, 1899. Dr. H. Tate, M.D."

As a sequel to this case, Dr. Anthony has been placed upon his trial for giving false certificates of death. He attempts to justify himself by saying that he had sometimes seen cases with Tate, and that, although he had given certificates at Tate's request and on his description, he had not known that they were not for patients whom he had seen. As the case is still sub judice, it is impossible for me to comment further upon it, but one item of evidence demands note. Dr. G. G. Eyre, of Claremont, called as a witness in defence of Dr. Anthony, testified that it was a common thing for medical men to give certificates simply on the word of the relatives that the patients had been seen by them, without taking any means to satisfy themselves of the identity of the case. This is justly regarded as a very unfair assertion to make, and the more so, from the fact that Dr. Eyrehappens to be the editor of the South African Medical Journal, and, as such, would be regarded by the public as an authorised exponent of the views of the profession-Certainly, no honourable man ever gives a certificate without fully satisfying himself as to identity. The Medical Association will probably take some steps toclear the profession from the imputation.

CONTAMINATION OF THE WATER SUPPLY.

Another local matter has made much stir of late. The water supply of Cape Town is derived from the summit of Table Mountain. Acting on the recommendation of the Medical Officer of Health for the City, Dr. E. B. Fuller. the City Council has lately applied for powers to exclude the public entirely from the catchment area, except certain limited paths. This step was dictated by a fear of possible contamination of the water supply by typhoid excreta, but as the area is nearly 500 acres, about twothirds of the mountain top, the proposal to deprive the citizens of their grand old mountain met with a good deal of resistance. The Cape Town branch of the British Medical Association discussed the matter in a fully attended meeting, and a resolution was carried by a very large majority, protesting against the new regulations as drastic and unnecessary. A deputation waited upon the Premier, whose sanction to new regulations of this kind is necessary, and urged the view of the Association. His reply was not altogether satisfactory, but it was understood that at least some modification of the regulations would be arranged. In view of the fact that the ascent of the mountain is rather too stiff a climb to make it likely that even the ambulant or convalescing cases of enteric fever would undertake it, and considering that the supply is derived from a multitude of trickling rills running over and through sand, exposed to strong sunlight and other bactericidal agencies, the sanitary zeal of the Council seems to be in excess of the requirements of the case. The matter has not been officially before the Colonial Medical Officers of Health, Drs. Turner (formerly of Guy's) and Gregory, but it is understood that they coincide with the opinion of the Association.

POST-GRADUATE TUITION.

The advisability of giving South African students the first year, at least, of the curriculum here, and of instituting a Post Graduate School is being mooted, and will probably be brought before the Medical Association shortly. Dr. Dodd, the President, initiated the idea in an address. We have a hospital of about 200 beds, a large dispensary, and Government institutions for mental disease, sanitation, and bacteriology, besides all the machinery for teaching physics and chemistry, with some provision for biology, and ought to be able to do something.

A NEW DISEASE AMONG MINERS.

Drs. Rogers, Brodie, and Hamilton, of Johannesburg, have lately published the results of some researches upon what they consider a new disease prevalent among mine Kafirs in the Golden City, and very fatal. They call it "Acute Specific Rhinitis," and consider it due to a diplococci, which they think is identical with Frænkel's pneumococcus, only more virulent. The morbid appearances, as shown in twenty-six cases, are a purulent rhinitis leading to meningitis, suppuration of the sinuses, middle ear suppuration, and parotitis. Croupous pneumonia was present in most of the cases, and there was generally peritoneal effusion. The cases with no pneumonia or very little were as fatal as the others. Dysenteric diarrheea generally occurred at the last.

Active preparations are being made for the South African Medical Congress, which will meet here in October next. Dr. C. F. K. Murray is the President-elect.

A Masonic Lodge named after Mr. Kendal Franks,

F.R.C.S., late Surgeon in Ordinary to the Lord-Lieutenant of Ireland, has been opened at Johannesburg.

The Operating Theatres.

ROYAL FREE HOSPITAL.

NEPHRO-LITHOTOMY IN A CASE OF OBSCURE DIAGNOSIS. -Mr. Battle operated on a man, æt. about 40, who had been suffering from obscure symptoms for some years; there had principally been frequent micturition with weakness and loss of strength, and occasionally an exacerbation with deposit of a yellow character in the urine and pain on micturition. He had been in various hospitals, where he had been told that he suffered from cystitis; he had previously been in the Royal Free Hospital, and had been subjected to examination under the X-rays, but without any satisfactory result. The opinion held at that time was that an enlargement which could be felt of the right kidney was possibly dependent on the presence of a calculus. The diagnosis was considered to rest between tuberculous and calculous pyelitis; against the tuberculous view was the fact that the patient had suffered for some years, and still showed no evidence of tubercle elsewhere; in favour of it was the comparative absence of pain or anything approaching a renal colic; in favour of calculous pyelitis was the fact that there had been intermittent attacks of the kind mentioned above, and that these attacks were usually ascribed to exertion, there had been blood in the urine, but it had not been a marked symptom. At his former visit to the hospital he had declined operation, but now asked for it, as his condition was much worse than it had been before. was passing large quantities of pus mucus, and was weak from this cause insufficient food; his condition was so unsatisfactory that operation was not immediately performed, but he was kept in bed and fed up. As the right kidney was large and a little tender, whilst the left could not be felt, it was considered that the right kidney was the seat of his trouble, and this was explored from the lumbar region. Examination of the kidney through the wound thus made showed it to be harder than natural, and not in a condition of pyo-nephrosis. The finger was easily worked through the substance of the kidney as far as the pelvis, the lining of which had to be divided with a director before a stone, which almost filled it, could be fully exposed; it was even then not possible to find its outline, for it was too large; forceps were placed on it with a view of its extraction en masse, but it broke down under their grasp, and it had to be extracted in large fragments. One of the extensions passed into a calyx, and there bifurcated so that, until the opening had been made larger, it was not possible to extract it. The kidney seemed remarkably healthy considering the number of years that the stone had probably been present. Exploration with the finger after removal of the stone showed that it had been fully extracted. A drainage tube was passed down to the opening in the kidney, and the wound closed with deep and superficial stitches. Mr. Battle considered that the kidney had suffered less than usual because the stone did not extend into the ureter so as to produce blocking of that, and had formed in such a way that it was practically fixed unless any special exertion shook it up. The patient had become such a hospital bird, going from place to place

and resting almost constantly, that attacks of irritation from this cause were rare.

THE RIVAL SYSTEMS FOR THE SANA-TORIAL CURE OF PHTHISIS.

ONE of the aspects of the present prominence into which the sanatorial system of treating tuberculous disease of the respiratory tract has recently sprung, although in truth the system is of older growth than yesterday's, is puzzling both to laymen and to medical readers of the wordy warfare waged between the apostles and their disciples of its two schools. These schools can be best recognised by the names of their individual Meccas, Falkenstein and Nordrach-Falkenstein with its apostle Dettweiler, Nordrach boasting Walther as its prophet. The Falkenstein method has lately been described in these columns. Its gospel preaches fresh air and rest in it in a recumbent position but under shelter for many hours a day; plenty of good food at mealtimes, with fresh milk added between them; windows open at night; walking exercise only in moderation and to medical order; absolute rest in bed when the temperature is above the normal; wine with dinner and supper, and spirits in fever. If the weather be wet and inclement the out-of-door life may be modified. The Falkenstein patients become feeding and dozing automata, many are benefited, and a considerable per centage recover. At Nordrach the gospel is according to Walther, and much more Spartan. Cold winds, rain, snow, or damp, make .no difference, Life must be spent in the open air, .moving about as much as possible, and with no extra .covering, as a rule. If wet, the clothes are allowed to dry on the body; if unwilling to sleep with a wide open window, the window is removed. The system of feeding is also more autocratic. Eat what is set before them

the patients must; if they cannot at the moment, they sit till they can; if they are sick they must return to table and begin again. The windows of the dining-room are kept wide open, and cheerful breezes -by no means to be called draughts-sweep in on most occasions over the table and past the occupants. We have seen the salt blowing off the edge of the plate when dining under this regime. Now many will, and do, object to the definite statements made by the apostles and adherents of either system as to its constituting the only right and proper method; how can both be right, yet neither wrong, while so different in conception? There is no doubt that both are right in so far as they are severally adapted for various different types of patients; one type of patient is benefited by the milder regime, injured by the harsher; and vice versa; still another type fails to react satisfactorily to either. drawbacks of sanatoria of the Falkenstein class lie in their large size and great number of patients, and the consequent inability of the physicians to exercise sufficient individual supervision, and in the extraordinary custom that persists in them (at least in Falkenstein and Hohenhonnef) of closing all the windows and doors when the patients are segregated together for meals in the dining-hall, and producing an atmosphere very inimical to large appetites, as we have had personal experience. only occasions on which the patients are brought together in one room are exactly those in which the freest circulation of fresh air is indicated, apart from the frequent disinclination for food brought on by it-at least, upon British and This drawback, of course, American patients. chiefly occurs in the winter and springtime; in summer the windows surely must be opened. The reason alleged is the repugnance of foreigners to air and so-called draughts in rooms; but, if made part of the treatment, those who refused to tolerate it would be better away. But here we have the fact that many of these places are conducted by limited liability companies, and the departure of patients for such causes might lead to decrease in the dividends. The Nordrach system, again, aims at individual medical control, and limits the number of inmates. But even this has a drawback, for it is seldom possible to instal a resident expert laryngologist because of the expense, and even the Nordrach treatment requires, it appears, some local assistance in laryngeal cases. It is extremely difficult to find out the truth as to the history of laryngeal cases of consumption in sanatoria. At Falkenstein many seem to do well. We believe that such patients are not persona grata at Nordrach. Attempts to obtain any statistical conclusions on the subject proved abortive; the question was not a congenial one at any of the institutions. Taking into consideration the after life history of those discharged cured or recovered from sanatoris, two interesting questions arise. Are such lives insurable ? If so, what extra premium would be advisable, in the most general sense? And should such persons marry afterwards,

if they have knowingly suffered from serious tuberulous lesions, but recovered? These questions will require to be answered in the near future, There is no doubt that both of these systems can actually abolish tuberculous lung mischief. Which of them is the better we are disinclined to say, because some benefit from the one, others from the rival method, and many from neither

THE PLAGUE IN EGYPT.

THE news that the plague has broken out in Alexandria will cause little surprise when viewed in the light of past experiences. Its progenitor, the Indian outbreak, which happily now seems to be declining, has led to an enormous loss of native life. The extent of the mortality may be illustrated by the fact that a fortnight ago the number of deaths from that cause all over India was returned as 953 "only," or "less than in any week since last July." With regard to Egypt, there can be no doubt that during the British occupation the sanitary condition of the country has been greatly improved, but for all that it may be questioned whether the country as a whole excels the average Eastern standard of public health. In other words, the plague having gained a footing in Egypt will not be readily ousted, for it is a disease that, above all others, is fostered and spread by an unwholesome popular environment. When, a couple of centuries ago, the malady slew its thousands in Great Britain, its virulence was due to the absolute ignorance of sanitary principles that prevailed in those days. Better attention to the laws of healthy living gradually abolished plague from the shores of the United Kingdom, just as within the memory of the present generation it has thrown off cholera. The practical lesson to be learned is that in both instances the malady is sent to the rightabout by good public health administration What Great Britain has effected in her own country, she has failed to accomplish in her vast Indian empire, for the prevailing sanitary conditions are simply deplorable. It now remains to be seen what will happen in the case of Egypt, where the British occupation has had merely a tithe of the duration of the supremacy in India. The disease was brought into Alexandra, so it is reported, by Russian pilgrims who arrived there after having touched at infected ports. The story has a ring not unfamiliar in the annals of the East, where religious rules and customs have so strong a hold upon the popular mind. It certainly brings home to a thinking man a sense of the huge responsibility involved in the empire of Greater Britain. Not only have vast territories to be conquered and held by the strong hand, but their sanitary salvation must be brought about in the face of deeply rooted ignorance and prejucice. Britain has already paid an enormous toll in the loss of life sacrificed to the sanitary dangers that lurk in every inch of Indian soil. It may, no doubt, be argued, on the other hand, that she has gone through a similar ordeal within her own walls, a proposition that cannot be seriously controverted. It is one thing, however, to pay

for one's own experience, but quite another to purchase the redemption of races that are not our own kith and kin. When the wider aspects of the prevention of disease are investigated the conclusion is unavoidable that no real advances can be made without a corresponding outlay of money. To bring up the vast cities of India to an average European standard of sanitation would involve an expenditure of Gargantuan size. Yet plague, to say nothing of other pestilences that stalk about by day and by night through these Eastern dependencies, can be excluded in no other way. To decide whether the game is worth the candle is a matter outside our province as a medical journal, and must be left to the later school of political economists, who will have the advantage of examining the cost of empire in the fuller light of modern preventive science. the task is a mere matter of skilled energy and monied administration was abundantly proved at Hong Kong, where the plague was rooted out by the British from foul and extensive native quarters. Imagination reels, however, at the thought of what a similar attempt would mean if applied generally throughout India. Fortunately, the bacteriologist has given us the key to the etiology of the scourge, and has provided a vast number of precise data as to the propagation of the specific bacillus by the soil, by wild and domestic animals, by vermin and by other Nothing can exceed the interest of this chapter of modern research, which showed how pigeons could distribute the disease from the housetops and ship rats convey the malady to far-distant ports. When all is said and done, however, we are still faced with the fact that plague was banished from England before the existence of pathogenic microbes was known. That is to say, its disappearance was due simply and solely to the gradual bettering of sanitary administration. Under the circumstances, the progress of the plague in Egypt will be watched with no little interest. In the Mediterranean there are many ports whose sanitary state is about as bad as bad can be, and should any of these be invaded by plague the world at large will doubtless be furnished with plentiful reminders of the danger of delay in the perfection of publichealth administration.

INFIRMARIES OR HOSPITALS?

THE conduct of the Bradford Guardians in appointing the two medical officers whose appointment has been so badly received by the medical profession in that city opens up a new vista in infirmary medical work. Let us try to discuss the matter in a fair spirit without calling in question either the technical right of the guardians to act as they have done, or the intrinsic fitness of the two gentlemen upon whom their choice has fallen. Hitherto it has been the universal custom to regard the post of medical officer to a Poor-law infirmary as one the duties whereof would best be discharged by a general practitioner, indeed, the duties are of such an onerous and irksome nature

as to indispose the consultant class of practitioner to compete for them. Otherwise it is evident that if the guardians had to choose between a Fellow and a Member of the College of Surgeons or Physicians their choice must, unless nepotism were rampant, fall upon the more highly qualified of the two. Under these circumstances it seems a pity that the guardians should have imported into their selection an element of controversy which was totally unnecessary in that, cæteris paribus, the gentlemen who have obtained their sanction would, under any circumstances, have come out at the top of the poll, always supposing that the guardians were actuated solely by consideration for the interests of the sick in their charge. It follows from what we have said, that whatever method of selection was adopted, these two candidates would have been chosen. But the selection amounts to a revolution in the principles which have hitherto guided guardians in the choice of infirmary medical officers. far from saying that the innovation is not one well worthy of approval, but it is of sufficient importance to challenge discussion on its merits. It has been our policy for years to advocate that workhouse infirmaries should be worked on hospital lines, that is to say, the senior medical staff should be composed of men whose professional status is such as to command confidence, and that the vast amount of clinical material which runs waste in these, collectively, gigantic institutions, should be made use of for purpose of clinical instruction. If the guardians individually would only take the trouble to investigate for themselves the conditions which prevail at hospitals where students are admitted they could not fail to be convinced that the presence of students is a great incentive to thoroughness of work on the part of the senior medical officers without, absolutely without, any drawback as far as the patients are concerned. If in future the infirmaries are to be made centres of medical study we cannot but approve of the selection of the highest possible order of physicians and surgeons as medical officers. On the other hand, if the guardians imagine that these men are going to render the same monotonous and unthankful services as those bitherto rendered by the ordinary workhouse infirmary doctor, they are egregiously mistaken. On the other hand, if these consultants imagine that the holding of these posts per se will give them consultant rank they, too, are mistaken; indeed, the mere fact of their supplanting general practitioners at a ridiculously low rate of remuneration will inevitably lead to a tacit boycotting. which will render their position the reverse of agreeable, and we cannot blame the medical men of Bradford if they set their faces against a departure which deprives them of sundry remunerative posts without any compensating advantage to the profession or to the public. Let us have a clear understanding with the guardians. Are they going to run the infirmaries on the lines of the general hospital, or are they merely trying to get a higher order of medical officer at a remuneration which the general prac-

titioner would despise? In any case we see no valid reason why the time-honoured custom of throwing open the appointments to public competition should be departed from. If the guardians like to append certain conditions, such as the possession of particular diplomas or degrees to the candidature, they are, we imagine, at liberty to do so, but above all let them avoid even the appearance of hole-in-thecorner manœuvres.

Aotes on Current Topics.

The Medical Education Question in South Africa.

THE question of medical education in South Africa is attracting a good deal of attention among the medical men in the colony. There are those who hold that it would be an expedient thing to start a South African medical school in Cape Town, while there are others who oppose the scheme entirely. It has also been suggested that a school of anatomy and physiology might be established as a beginning, but the obvious arguments advanced against the proposal are that the undertaking would be a very costly one, and inferior in appliances and accessories to the great European schools, while it is doubtful whether the South African students would care to avail themselves of its privileges. The situation is summed up by Dr. Anderson, of Cape Town, who expresses the opinion that the question of founding a South African medical school may be safely adjourned for a generation. "Our population," he says, " is too small to enable us to have anything but a make-shift medical school, and I do not think that I am wanting in loyalty to South Africa when I say that the gain to our professional men from some years of close intercourse with the great centres of life and thought must far outweigh the somewhat narrow advantage of being able to do everything for ourselves." It must be conceded that the views expressed by Dr. Anderson closely coincide with those generally prevalent among medical teachers in London. To found and organise a medical school and equip it in accordance with all modern requirements is a most costly undertaking, so much so, that it is often quite impossible to make these undertakings paying concerns. We believe that in at least one medical school in London not only do the teachers fail to be paid for their services, but from time to time they are called upon to contribute to a fund for the maintenance of the school. Again, among the large schools, despite the ample entry of new students every year, the payments of the teaching members of the staffs are much diminished owing to the heavy expenditure demanded in order to keep pace with the requirements of modern medical education. Thus from a financial point of view, medical schools in London are by no means in favour, and regarded in the same aspect, it seems difficult to comprehend how, even with the best prospects, a South African Medical School could become self-supporting. There

is nothing, however, to prevent a South African millionaire building and endowing a seat of medical learning in Cape Town, if he felt so disposed, and thus perpetuate his name and good works after the manner of the philanthropist Johns Hopkins, of Baltimore.

Diabetes in Children.

DIABETES is acknowledged to be a very rare affection in children, and the paper, therefore, by Dr. Townsend, in the Boston Medical and Surgical Journal, for May 11th, in which the notes are given of five cases is undoubtedly of interest. In one case the child was only one year and eleven months old, while the oldest was nine years of age; a fatal issue occurred in all. Prout and Meyer, in a series of 700 and 380 cases of diabetes respectively, each met with only one case under the age of ten years. Again, Wegeli has collected 108 cases of the disease in children, among whom there were three children whose age was no more than three months each. In children diabetes is a much more rapid disease than is the case in adults, and the prognosis is always bad. In the series collected by Wegeli the shortest course of the disease was in a child, aged two years and nine months, who was only ill four days and then died of coma, while the longest case did not prove fatal till after the elapse of four years and a half. In the author's cases the duration of the disease varied from two to fourteen months. Attention is drawn in the paper to the fact that the initial symptoms are incontinence of urine, due to polyuria. nervous irritability, and great thirst, while strength, flesh, and colour may be retained till nearly the end. So far as treatment was concerned, the author gave his patients codeine, and enforced a strict anti-diabetic diet. But in no instance did any real improvement follow, although occasionally a diminution was noted in the quantity of sugar excreted. Lancereaux believes that the occurrence of diabetes in children is due to a relative insufficiency of the pancreas, owing to a want of development of that organ.

Trichinosis in America.

IT is curious to learn that a disease like trichinosis is still met with. While in this country the probability is that no case has been seen for many years. yet in America, we gather from Professor Osler, that the disease is by no means infrequent, and sometimes even assumes an epidemic form. Professor Osler has paid a large amount of attention to the subject, mainly from the point of view of the differential diagnosis of the malady. When occurring in an extensive outbreak he states that there is no difficulty in the diagnosis, but just the reverse is the case when it occurs in sporadic form, and it then happens that many of the cases are overlooked. The disease, the clinical features of, which trichinosis most closely resembles, is typhoid fever, and in order to distinguish between the two it is essential to know the three main features by which it is possible to arrive at a differential diagnosis. According to order these features are—(1) muscular pains; (2) œdema; (3)

leucocytosis and eosinophilia. Muscular pain is universal in trichinosis, and is rarely if ever present in typhoid fever; again, in trichinosis there is usually ædema which is most marked in the eyelids and overthe eyebrows. Lastly, leucocytosis and eosinophilia present in trichinosis is not known to exist in typhoid. All these points, of course, are of interest, but they are altogether beside the question when it is remembered that trichinosis is an easily preventible disease,and with the adoption of the most ordinary precau tions could not occur. Meat which is infested with trichinæ can be rendered quite safe by efficient cooking; the parasites are killed by a minimummoist temperature of 170 degs. F., but if a lower temperature than this he employed for the cooking, the parasites will be afforded the opportunity of making a new start in the tissues of thosewho partake of the meat. It has been stated that trichinosis seldom occurs in England, not because undercooked meat is not eaten, but because the trichina does not happen to infest British pigs. This is possibly the case, but if so, is there any reason why the parasite should be allowed to infest the pigs of any other country?

The Rheumatic Heart.

Not long since Drs. Lees and Poynton calledattention in a valuable communication to the suddenand well-marked dilatation of the heart which can be made out in patients suffering from acute rheumatism_ such dilatation subsiding as the disease disappears. In a further communication embodying the resultsof pathological researches on a fatal case of the kind, Dr. Poynton shows that the dilatation in question coincides with the existence of a myocarditis which may occur quite independently of either endo- or pericarditis. Hitherto the marked increase in the area of precardial dulness has generally been attributed without further inquiry to pericarditis and the murmursinduced by the dilatation have been too readily putdown to endocarditis. It is highly important that current views concerning the pathology of the rheumatic heart should be revised in the light of these researches. Cases are on record in which exaggerated precordial dulness has led to a diagnosis of pericardial effusion, and in more than one instance attempts have been made to drain the pericardium, of course with a disastrous result. Dr. Poynton was able to adduce microscopical evidence in abundance, pointing to the existence of degenerative lesions in the myocardium, and it seems likely that these constitute the source of the dilatation, itself a consequence of the weakening of the cardiac muscle. The materies morbi is at present referred to the hypothetical toxin elaborated by a not less hypothetical micro-organism, but bearing in mind that one of the most salient and most constant features of acute rheumatism is the presence of lactic acid in the blood, one is at a loss to understand why the damage should be localised in one particular part of the muscular apparatus. But it is possible that it is not thus localised, and in any event it cannot safely be affirmed in the absence of concurrent examination of other voluntary and involuntary muscles. It may well be that the degeneration which attacks the heart muscle is only part and parcel of a general process involving the muscular system as a whole. There are several points in the clinical history of rheumatism which lend colour to this assumption, in particular, the extreme muscular weakness and atrophy which characterise an acute attack of the disease. We must leave it to those who are fully equipped for such laborious investigations to work out the pathology of this interesting subject; but, in the meanwhile, it is highly desirable that the general practitioner should reconsider his views of rheumatism in so far as it affects the heart, because both diagnosis and prognosis cannot fail to be profoundly modified as the result of the fresh light that has already been thrown on the subject of cardiac lesions in association with rheumatism.

Certificated Opticians.

THE Corporate and Medical Reform Association are actively moving in the matter of bringing professional pressure to bear upon the General Medical Council with a view to that body taking steps to deal with the question of the certification of opticians by the Spectacle Makers Company. For this purpose a special fund has been opened by the Corporation in order that the campaign of resistance may be brought under the notice of all members of the profession. The object, of course, is a worthy one, though we may doubt whether the General Medical Council will concede that the matter concerned really comes within the purview of their functions. Again, the contemplation of a legal tussle with such a powerful company as that of the Spectacle Makers' would be more than likely to weigh heavily in the balance were the Council disposed to adopt strong measures. We believe that the company in question has emphatically determined to fight for the maintenance of their position to the bitter end, and to protect the professional rights of all of those concerned with them in the undertaking. Under these circumstances, therefore, it would be only natural were the General Medical Council to hesitate before embarking upon a course which had every prospect of leading to prolonged and exceedingly costly litigation. Thus, while the Corporate and Medical Reform Association a e quite justified in, and to be commended for, doing their best to impress upon the General Medical Council that the matter is one for official interference, yet, on the other hand, it does not seem to be at all possible that anything of importance will come of their protest.

The Physiology of Insomnia.

Insomnia is the apparage of certain nervous temperaments, but it is precipitated and predisposed to by a large number of dietetic and other errors of a distinctly remediable nature. In women tea drinking, and in men tobacco, are responsible for much of this nocturnal excitability to an extent which the sufferers little dream of. Then, too, the condition of the stemach has much to do with the vascular supply of

other hand, it be empty, the night's rest is likely to be disturbed. These are well recognised and removable causes, but there are other, more subtle, factors which are equally capable of preventing sleep. One is the intense desire to sleep coupled, it may be, with the fear that sleep may not come. Nothing probably acts so efficiently as a sleep preventer as the extremedesire for it. The importunate ego wanders restlessly into the various chambers of the brain, testily inquiring why the cells are not at rest as per order, and the half-dormant cells rouse themselves to offer excuses, and then the irritable ego retires into its cerebral lair, watchfully apprehensive lest its subordinates should not comply with its orders. The muscular system, as represented by the cells in the motor area, resent the intrusion and give vent to their dissatisfaction by irregular contractions, manifested by an attack of fidgets, which the wrathful ego is powerless to control. The sufferer's only chance is to give his Me an occupation of some sort. Give it something to do, some calculation to control, some problem to elucidate, and forthwith, the moment its vigilance is relaxed, the subordinate faculties turn off the light and there is peace. This is the general principle underlying the tricks suggested by popular usage for wooing sleep, the success whereof depends upon the ability of the subject to enforce a sufficient amount of domestic discipline.

A Literature of Snippets.

THE Saturday Review deplores the popularity of what is described as "a literature of snippets." Instead of reading Ruskin, Gibbons, Shakespeare, or Spencer, the average British reader is satisfied with an intellectual meal composed of snippets, mere extracts from current events and annotated descriptions of physical and mental monstrosities. Is there not a somewhat similar tendency in medical literature? Isthere not a certain section of the profession which is satisfied to be fed with snippets from contempora-They do not require to know neous publications. much about anything but they want to know something about everything. It is hardly necessary topoint out that such knowledge is valueless for all practical purposes. We cannot know too much about anything, but it is very possible to know too little, and in medicine above all too little knowledge is a very dangerous thing. value can it be to know that Dr. X. in some out of the way place has prescribed such and such a drug in a particular disease. The snippet does not give sufficient data to enable the reader to judge whether or not he is worthy of credence, and the mere intimation that a surgeon in Alaska has successfully (?) removed the stomach will not materially assist the reader in treating his cases of dyspepsia. The only valuable form of medical literature is the monograph in which the author's professional status is set forth, and he gives his reasons for arriving at certain conclusions. When this is transmogrified into a "snippet" its educational value is lost, and we have instead a bald statement of premises and conclusions. the brain. If the stomach be over full, or if, on the Let us beware of this tendency which degrades

medical literature and impairs the logical faculty of the reader.

The Purity of Drugs.

PHYSICIANS may prescribe, but, after all, the worth of the remedies they order is determined by the activity of the drugs that are put into the bottle. We are happy to believe that with the average respectable chemist their patients are safe, but a slight consideration of the matter from the point of view of probability must convince the most confiding customer that now and then he does not get what he pays for. Nay, more, in the rare instances in which local authorities have troubled to test pharmaceutical products a fair proportion of convictions have followed under the Sale of Food and Drugs Acts, indeed, a more strenuous application of those salutary measures is much to be desired in the interests of the public. What can be more desirable, for instance, than the systematic supervision of the purity of drugs used as medicines? Yet in the vast majority of cases no samples are taken by the sanitary boards of our local authorities. Perhaps the new districts created by Mr. Balfour in the metropolis will find time to look into this important matter, and set an example to the Provinces. In America, the Massachusetts Board of Health analysed 1,380 samples of drugs in the year 1896, and found 156, or 11.3 per cent., impure. The percentage of similar adulterations during the four years preceding was 11 per cent. Among the drugs implicated were spirits of nitre, rhubarb, and vinum ipecacuanhæ. Clearly the matter is worthy of a little more attention on this side of the Atlantic.

The Disinfection of Schools and Churches.

THE Medical Officer of Health of Halifax, in view of a possible epidemic of small-pox, suggests that advantage should be taken of the holidays to disinfect the elementary schools, and he urged that this measure of protection should be extended to Sunday schools, churches, chapels, and other places of public resort. This is a very valuable suggestion, and one that calls for adoption and imitation. As a rule the flooring of schools and churches, &c., is of soft absorbent wood, which attracts and retains dust in a very marked manner. When the floors are moistened they invariably give rise to emanations of a highly odoriferous character, testifying to their richness in organic detritus. Periodical disinfection with sulphur or formal would undoubtedly tend to purify and sweeten the atmosphere of such buildings, and as churches are notoriously ill-ventilated it is not excessive to ask that steps may be taken to protect our bodies against infection while the higher part of us is being attended to.

The Tomato as a Tonic.

THE tomato not only now enjoys great popularity as a vegetable, but quite recently experimentation has shown that its juice is very valuable as a blood tonic. During the recent Hispano-American War the juice of the tomato was extensively utilised for

keeping the American troops in health, with results which at the time were regarded as very satisfactory. Some prejudice will probably always interfere with the free use of the tomato, on account of the fact that some silly person was once audacious enough to say that it caused cancer. But there has never been one iota of evidence brought forward in support of this absurd notion, and the suggestion is altogether preposterous. On the other hand, it would be difficult to find a more easily digestible, novrishing, and wholesome vegetable than the tomato. Moreover, the well-known colour and form of tomatoes adds to the attractiveness of culinary dishes, and when eaten in the raw state they are even more nourishing than when cooked.

The Inebriates Act.

For some time past it has been more and more evident that the new Inebriates Act, from which the friends of temperance expected so much, has not vet fallen on its feet. It is all very well to sentence the police court victims of drink to so many years' detention in a "home," but it becomes a species of burlesque opera sentence when no place of the kind exists whither they may be sent. One of the chief flaws in the Act, as some of its critics pointed out at the time of its passage through Parliament, was to be found in the lack of provision of proper detention. Before long something practical will have to be undertaken by Her Majesty's Government in that direction. No doubt the step will mean the expenditure of a very large sum of money; but it is likely that, in the long run, it would not cost the country more than that of maintaining prisoners continually convicted under the present system. So far as London is concerned, the deadlock was last week exemplified in several cases. One woman could not be taken into the only available institution because she was not a Roman Catholic. One of the magistrates kept a woman in prison several weeks while inquiries were being made. He said that there were only three such homes as those contemplated by the Act. Two were impossible for the prisoner, on account of her character and religion, while the third refused admission because the County Council would not contribute to the funds of the establishment.

Sanatoria for Tuberculous Patients in England.

The open-air treatment of phthisis has "caught on" so much with the profession as well as with the public that a boom is beginning in the establishment of sanatoria for the purpose. One small company that we know of, on a small capital, is paying its lucky shareholders upwards of ten per cent. on the outlay, and there is no doubt that, under proper management, institutions of the kind offer good prospects of paying a satisfactory dividend. Now that the demand has been created in this regard there will probably be no lack of money in order to meet it, on the part of the investing public.

Glaise v. Christie.

UNDER the title "A Nurse's Action for Inadequate Instruction," we alluded in our last issue to a claim for damages based on alleged non fulfilment of contract and fraudulent misrepresentation brought by Miss Glaise, an aspirant nurse, against Dr. Christie, of Bedminster. We are pleased to learn that the jury, without any hesitation, gave a verdict in favour of the defendant. Indeed, in view of the evidence it would have been difficult for them to do otherwise. We gather from the later reports that the plaintiff only remained in Dr. Christie's cottage hospital for rather less than a week, and left in a huff, so that she was hardly in a position to affirm that the instruction was adequate or otherwise. While we congratulate Dr. Christie on the issue of the action we cannot but disapprove of any scheme for training nurses which is based upon a three months' or even six months' course. Such a course of training, even in a large and well-appointed hospital, must needs be miserably inadequate, and as the public cannot be expected to enter into these details when engaging the services of a nurse it is much to be desired that the right to exercise the functions of a trained nurse should be restricted to women who have passed through a recognised and sufficiently protracted curriculum at a public institution of adequate size. If nurses are to be certificated on the strength of a short and perfunctory course, the position of trained nurse will soon carry no more weight than that of the certificated masseuses who have been manufactured by the gross in the interests of individual practitioners.

The Dundrum Dispensary Election again.

This bone-of-contention district now awaits its fifth effort at the parturition of a medical officer. We need not recapitulate the very peculiar circumstances under which four election meetings of the guardians have been already held without result. At the last one we understand that the first two votes among the favoured candidates were taken by ballot, but the final vote for the successful candidate by open voting. The Local Government Board has decided that this method is illegal, although it is that which has been followed for the past twenty years, and has ordered that a new election shall be held and the whole proceedings gone over de novo.

The Meeting of the General Medical Council.

THE Session of the Council opens to-day, and its Executive Committee met yesterday to arrange The budget of the President is very business. full of important business, and it is likely that the meeting will extend beyond the week. Among the items for discussion are: the proposed increase in the disciplinary powers of qualifying bodies, the preliminary examinations, the examinations of the Apothecaries' Hall of Ireland, the Medical Aid Associations, the sham diplomas of the Spectacle Vendors' Guild and suchlike, and several penal cases. There will also be a renewal of the protest against the concealment system of transacting the Council's business initiated by the new President.

If any of the larger questions in which the profession is interested be settled no one will grudge the heavy cost of a long sitting.

The Institute of Preventive Medicine.

THE munificent bequest of a quarter of a million by Lord Iveagh to the Jenner Institute has been the subject of an application to the Court of Chancery. The donor wished to appropriate the income of the grant to research as distinguished from treatment of disease, and with this intention a modification of the original scheme of the Institute was proposed. The result of the application to the Court on this occasion was a postponement.

A Certificate of Sobriety.

Not everyone charged by the police with drunkenness is sharp enough to take the bull by the horns and get a medical certificate of non-ebriety. This, however, was what a man at Wycombe did last week when threatened with a prosecution, and Dr. Nicholson, whom he consulted, was able to certify that he could co-ordinate his movements well, that he could walk a line on the square step, and could repeat sentences clearly. Under these circumstances, the doctor expressed the opinion that he was not, at the time of giving the certificate, drunk and incapable. Under these circumstances, the magistrates could hardly do otherwise than dismiss the case.

Doctors at the Lowest Tender.

Our readers are aware that the Local Government Board for Ireland has recently introduced into the Union drug contract system a new arrangement by which the Board itself fixes the standard price of the drugs and the contractors estimate for the supply by stating the discount which they will allow off the total of the official prices, such discount being, in some cases, as high as 50 per cent. It is reserved for the Coleraine Guardians—a canny northern Board to propose to extend the same system to the doctors. They suggest that the Local Government Board shall fix the maximum in each district and that competitors shall tender for as much less as they will accept. The arrangement would be at least economical, for we could offer to the Coleraine Board a few legally qualified practitioners who would be very ready to go for 75 per cent. less than the official price. Heaven help the unhappy and friendless sick poor.

A LIVERPOOL contemporary states that Dr. Crawford is about to commence legal proceedings against Drs. Taylor and Whitford in respect of their allegations concerning his conduct as Medical Officer of the Cancer Hospital, as well as against Truth for re-editing and commenting upon the same. We trust that this report is correct, as, in the absence of anything approximating a satisfactory inquiry by the management of that institution, the Law Courts afford Dr. Crawford an unexceptionable opportunity of clearing himself from the damning inuendoes which have been circulated on his character.

The Dublin Public Health Salaries.

WE noted last week that the guardians of the South Dublin Union had intimated to all their public health officers that they must look for their salaries in future to the urban authority, i.e., to the Corporation. We understand that the latter body has accepted the liability, and that in future all such salaries will be paid directly out of the borough fund, and not pass through the hands of the guardians.

A SPECIAL meeting of the Governors of the Royal London Orthopædic Hospital will be held on Thursday, June 8th, for the purpose of considering and amending some of the bye-laws. With at least one proposal we cordially agree that no one shall be allowed to vote, "who at the date of his election to the committee, shall have been a Governor of the hospital for a period of less than twelve months." Had such a rule been in existence the scandal at a Liverpool hospital referred to in our last, by which voters were created just before the meeting, would be impossible.

WE regret to learn that Mr. Phillips, practising in Commercial Road, E., has been the victim of a cowardly assault, followed by robbery. He has, however, the satisfaction of knowing that two, at any rate, of his supposed assailants, have been committed for trial on a charge of highway robbery with violence.

MB. NORMAN HAY FORBIS, F.R.C.S.Ed., of Tunbridge Wells, has been admitted to be one of Her Majesty's Royal Company of Archers and Bodyguard for Scotland.

SIR RICHARD DOUGLAS POWELL, Bart., has been elected President of the Clinical Society for the ensuing session, and Mr. Charters Symons, M.S., and Dr. Percy Kidd have been elected secretaries.

Dr. Lippmann, one of the Professors in the University of Vienna, has discovered a new element. Full details will be brought before the Vienna Academy of Science. The matter has aroused much interest in scientific circles in connection with the recent discoveries in England.

We regret to learn that the health of Sir Francis Laking, M.D., Apothecary-in-Ordinary to Her Majesty the Queen and His Royal Highness the Prince of Wales, is in an extremely critical condition. Sympathetic messages from Royal patients are arriving daily at his riverside residence at Marlow, where he is lying seriously ill.

Scotland.

[FROM OUR OWN CORRESPONDENT.|

GLASGOW UNIVERSITY AND ITS STUDENTS. — The students of the University are directing the attention of the professors to the fact that Anderson's College professors encourage their students by giving prizes both in books and instruments, to their successful students, whilst the university professors content themselves and ease their consciences by giving certificates of merit, and in a class of from 80 to 100 there may be at most two or three first-class certificates; also in the matter of gold medals Glasgow University is far behind the Edinburgh

University, for every one given in the former five or The Glasgo six are given in the latter school. University students think that the professors with their large incomes might devote a few pounds in the pur-chase of suitable as well as useful prizes, and thus encourage students and show their appreciation of the work done as well as the interest and zeal of students in their classes. The final examina-tions are shortly to begin, and consequently many are the wailings of the likely-to-be candidates, especially as the wards, or certain of them, from now become hidden mysteries as regards the cases which they contain. This has become imperative, as there is always a tendency for laggards to suddenly assume to be very attentive in the wards when they are likely to be examined in the clinicals. It is reported that this year candidates are to be treated to the presence of additional examiners from England on behalf of the General Medical Council to see that Scottish degrees are not too easily obtained in medicine. It is said of one of these assessors that after returning from a recent examination in surgery in Glasgow, he reported to his Council that as far as he could see the cases which candidates were asked to diagnose were very simple and required no knowledge of surgery, and cited a case which he stated was a simple one of epithelioma of the lip, in which there was no credit in "spotting." The Secretary to the General Medical Council at once communicated with the Glasgow examiners asking an explanation. The reply was that the examiners had carefully looked over the list of cases shown to students, that there was no case of epithelioms of the lip, but that there had been one of a hard specific sore of a different kind which the student had diagnosed correctly, and probably this was the case referred to by

Manchester.

[FROM OUR OWN CORRESPONDENT.]

ROYAL INFIRMARY.—Much interest is being taken in the forthcoming election to fill the vacancies caused by the resignations of Professor Leech and Dr. Little. The candidates for the post of Assistant Physician are Dr. Brockbank, Dr. Kelynack, Dr. Reynolds, and Dr. Williamson; while for that of Ophthalmic Surgeon Dr. Hill Griffiths and Dr. Emrys Jones are applying.

OWENS COLLEGE.—A course of lectures on "Tropical Diseases" is being given during the summer session by Dr. Graham Steell. At present no arrangements have been made for adequate clinical instruction in this im-

portant department of medicine.

MEDICAL STAFF CORPS.—The members of the Manchester Volunteer Medical Staff Corps have been having a busy time at Netley. Fortunately, the weather has been more favourable than in the North, and full parades have been possible. The current number of the Owens College Union Magazine give a number of illustrations of the students' company during their Easter week under canvas, and several well-known medicals are readily recognised.

LANCASHIRE MILL LIFE.—Mr. Allen Clarke, who has had a practical experience of the factory life of this district, in his recent work on The Effects of the Factory System, clearly shows that "The system is unhealthy, dangerous, bad for mind and morals, has an injurious effect on family life, units woman for motherhood, and is causing the record of Lenesshire to deteriorate."

is causing the people of Lancashire to deteriorate."

WORKHOUSE NURSES.—The Northern Workhouse
Nursery Association has just issued its eighth annual
report. Its objects are to promote the employment of
trained nurses in the workhouse, and to supply trained
women to boards of guardians. There are now forty-five
union hospitals employing seventy-seven nurses supplied
by the Association.

THE Infectious Diseases Notification Act (1889) Extension Bill has emerged from the committee stage in the Lords, and the third reading has been put down for June 1st.

THE HOSPITALS ABUSE ACT.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

Sie,—Why does all the boasted desire to prevent abuse of charities avail nothing? The answer is too painfully evident to those who quietly watch the moving spirits with their background of selfish insincerity. Yes, were such not the case it would be very easy indeed to stop the ever-increasing evil of certain classes of society to impose upon the benevolent. Take for instance the abuse of that charity now troubling the minds of the charitably disposed benefactors. I refer to the abuse of the hospitals. Yet, there is a large sum here to be stealthily melted away in Central Boards and

Organisations.

If the money lavished upon hospital charities is to be applied to the purposes for which it is intended, then all that is necessary is a strict economy inside the hospitals and a short Act of Parliament outside, the rough outlines of which should run: Every person applying to a hospital for assistance shall sign a declaration form stating his name, address, occupation, weekly and annual income. Every person giving a false name or address shall be liable to imprisonment with or without hard labour for a period of not less than seven days nor longer than one calendar month. Every person understating his weekly or annual income from all sources shall be liable to a fine not exceeding 40s., and a further sum of 42s. shall be imposed for the services obtained in consequence of the declaration form on which he had declared falsely. The monies derived from fines to go to the police courts and the fees charged for services rendered shall go to the funds of the hospital. In no case shall the surgeon or physician benefit by the false declaration fines or fees for service. Every hospital shall appoint a sufficient number of investigation officers to carefully inquire into the statements made upon the declaration forms, and whose duty it shall be to take immediate proceedings against every false declarant. Should any hospital fail, or refuse, or omit to appoint such officers it shall then become the duty of the Local Government Board to take such steps as may be necessary to appoint and attach to that particular hospital the officers before named, and to charge their salaries and ex-penses upon the hospital. Should any one of Her Majesty's subjects become aware of any case in which no proceedings have been taken within one week after the false declaration, then such one of Her Majesty's subjects may upon depositing £10 in a police court, as guarantee of costs should he fail to obtain a conviction, proceed against the false declarant as if he were the hospital officer, or he may take action against the hos-dital officer for neglect of duty and recover from him the sum of £10 for his personal inconvenience, together with any proper legal expenses as between client and solicitor. In the event of any person requiring immediate attention the hospital may give that attention and detain the patient in hospital when necessary and with his consent; or in the event of the patient being incompetent so to decide then he may be detained with the consent of those lawfully responsible for his maintenance, and who shall be responsible for his maintenance, and who shall be required to refund to the hospital a reasonable charge for such maintenance and services as may seem fair and consistent, having regard to the patient's social and financial position. I would suggest as a wage limit, say, 30s. a week for a man without dependents, 40s. a week for a man with dependents, and 3s. a week for every child over the number of two. I would make it a serious offence for any investigation officer to receive bribes or to in any way suffer this Act to be defeated so far as his duties are concerned. Now, just for a moment, think how many investigation officers would be required for one of even our largest hospitals, and I believe the reader will agree with me that not

more than two would be required after the Act had been in force for six months. The importance of this subject is so great that I feel sure you will pardon the liberty I have taken in thus trespassing for so long upon your valuable space.

I am, sir, yours truly,
ROBERT HUGH HODGSON.

Rye Lane, Peckham, S.E.

ON SERUM INOCULATION.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

(Without prejudice.)
SIR,—I have just arrived in this country and have read your editorial note on my communication in your issue of March 15th on the above subject. Permit me to say that the writer of that note has entirely mistaken the question which I have put before the profession about the compulsory inoculation of cattle for diagnostic purposes. I shall, therefore, put it in a

simpler form-namely :-Koch's original serum for the cure of phthisis having been proved to aggravate the disease, and to cause the deposit of new tuberculous nests in the organism, Koch modified the serum, which has been proved, by veterinary surgeons, to be a sure means of diagnosis in cattle. Well, granted that the modified tuberin cattle. Well, granted that the modified tuber-culin (T.R.) possesses all the properties which its advocates claim for it as a sure diagnostic agent, no fault could be found with it as employed by the cautious Glasgow people in cases of animals which exhibit tuberculous symptoms, or are otherwise ailing. But the question which I have before the profession is as to whether we are justified in inoculating all dairy cows which are perfectly healthy? The question has been forced upon our consideration by the report of a committee of experts at the Dairy Congress on Tuberculosis in August, 1898, that "Koch's new tuberculin (T.R.), although free from the lethal properties of the original fluid, nevertheless contained a poison which lowered the heart's action, spreads tubercles to the lymphatic glands, and favoured the development of specific inflammation. This substance we are ordered to inject into healthy cattle, notwithstanding that experiments on a large scale have shown that 14.6 per cent of healthy cattle become tuberculous the following year after inoculation. Is there no reason to fear that the wholesale inoculation of healthy cattle may produce far-reaching disastrous effects by poisoning our food supply?

In my visits to the various European educational centres, I shall discuss the subject with some high

authorities. Should I find that my apprehensions are groundless I shall most cheerfully report it in your columns.

> I am Sir, yours truly, J. R. WOLFE, M.D.

Hotel Metropole, London, May 25th, 1899.

Our correspondent bases his arguments on highly questionable data. It is precisely for the purpose of distinguishing between healthy and apparently healthy cows that the test is proposed, and post-mortem examinations have almost invariably confirmed the result yielded by the test. Tuberculin cannot possibly convey infection, though conceivably it may render existing lesions manifest, a result to be desired in the public interest.—ED.]

THE APPOINTMENT OF MEDICAL OFFICERS TO THE BRADFORD WORKHOUSE.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

-The communication of Dr. Crowley and Mr. J. B. Hall, which appears in your issue of the 24th inst., anent the above question is a puerile plea in justification of their action. The Bradford Guardians action is not original. They are merely following the example of Manchester and Birmingham. In discussing the two appointments they must be taken sepa576

rately, in order that they may be their proper light. Dr. Crowley has pointed Medical Officer to the workhouse. be viewed in heen He is the only officer that the Local Government Board will recognise, and he is responsible for the medical supervision of the whole institution. Mr. J. B. Hall has practically no locus standi at the workhouse so far as the Local Government Board is concerned, although the Guardians may say otherwise. He is merely an assistant visiting Medical Officer. The previous Medical Officer to the workhouse was in receipt of a salary of £120 per annum. Dr. Crowley has accepted the appointment at £150 per annum, and his responsibility and duties are no less than those of the previous medical officer, although the Guardians have furnished him with more assistants. It is not often we find the assistant medical officers in receipt of a salary equal to that of the principal medical officer. The Guardians, in making these appointments, gave as their explanation for doing so that they intended to provide the workhouse patients with the best possible medical attendance; also that they intended to make the workhouse infirmary resemble, in every respect, a general infirmary. The Guardians say that their visiting medical officers are not to receive a salary but an honorarium. They are afraid to call a spade a spade. Now if these appointments are honorary the guardians have practically introduced medical charity into their workhouse infirmary. If the appointment of medical officers is not honorary, and it can claim no such appellation, it has been accepted at a salary which is far from adequate and is not in consonance with the responsibility attached to such an office. The Bradford and West Riding Medical Union has made much of the arbitrary manner in which the guardians have made these appointments, and in doing so it has lost sight of the great principle at stake, namely, the introduction of medical charity into the Poor law service.

I trust that the Medical Press and Circular will give space for the discussion of this question. I may say that two contemporary journals have adopted a biased atti-tude which almost amounts to bigotry in refusing to open their columns for the discussion of an abuse which

may have far-reaching consequences.

I am, Sir, yours truly,

May 25th, 1899.

H. B. S.

Laboratory Aotes.

"S. N." STOUT.

It is nearly a quarter of a century since we first examined this article, and found it what the brewers claimed, a pure beer and pleasant to the palate. The methods of manufacture in this, as in most articles of commerce, have varied considerably during the interval, and we approached the analysis after so long a period with some curiosity. On examining present samples of the "S.N." stout (Waltham Brothers, Stockwell), our analysis gave the following results:—The specific gravity at 15.5 degrees Centigrade was 1025 (water = 1,600). The amount of alcohol was equal to 4.8 per cent. of absolute alcohol by weight (=10.54 per cent. proof spirit by volume). The total solid residue, dried at 100 degrees Centigrade, amounted to 7.7 per cent., and this, on ignition, yielded an amount of ash equal to 0.3 per cent. on the original sample, testifying to the absence of an excession. sive amount of salt. The acidity was determined by trituration with a standard alkali solution, and was equivalent to 0.3 per cent as acetic acid. With these data before us we are enabled to affirm that "S. N." stout is, as formerly, a well-made pure article, eminently adapted for the use of those who, from taste or for therapeutical reasons, require a stimulant of this class, the proportion of alcohol is moderate, its keeping qualities are good, and it may safely be recommended for general use.

Literature.

THE LUMLEIAN LECTURES. (a)

THE author commences with perhaps the most difficult part of his task, namely, the treatment of cardio-vascular neuroses, or functional affections of the heart, which he aptly defines as "an increased sensibility and disordered action of the heart not dependent on structural change." These, as he points out, prove, as a rule, very refractory to treatment, more especially cases of tachycardia, and in their management reliance should be placed less in drugs than in the removal of all possible sources of reflex irritation. The use and abuse of digitalis and of baths and exercises, are judiciously and ably discussed, and an interesting table is given of fourteen cases of infective endocarditis, collected from various sources which have been treated by anti-streptococcus serum. Unfortunately, the results are not as favourable as one could wish, though there were three recoveries, which is a better proportion than can be claimed for other methods of treatment.

For the better understanding of neurosis of the heart, two coloured illustrations are given, showing diagram-matically the innervation of the heart.

Those who have already heard or read these lectures will be glad to have them published in a handy little volume for future reference, and by those who have not, they will repay perusal.

BOLLINGER'S PATHOLOGICAL ANATOMY. (¿)

THERE are few departments in medical science of which it is so difficult for the student and practitioner to acquire a sound and comprehensive knowledge as morbid anatomy, and there are also few subjects so difficult to illustrate satisfactorily. We accordingly consider that the medical profession is much indebted to the publishers for these volumes, which are issued simultaneously in England, America and Germany. Though there are already atlases of great excellence in the field, their high price, in some cases, practically prohibitive, prevents their general use. In the present instance, however, this objection does not apply. At a moderate price, we might say at a remarkably low price, an admirable series of coloured plates, with accompanying text is supplied, so that no practitioner or student can now complain of such prohibition. These volumes con-tain, in all, 132 coloured figures and 35 drawings in the text. These include all the common diseases both of the organs usually examined and also of the genital organs, bones, joints, &c. There are included, in addition, conditions more rarely met with, such as acute yellow atrophy of the liver, toxic enteritis and nephritis, &c. The ground covered is thus extensive, and after going carefully over all the plates we can say that there are very few indeed which are not good, while most are excellent. And it seems to us that the excellence is most marked in the case of the lesions of rarer occurrence, and in the case of the organs of which the morbid changes are most difficult to reproduce. In connection with the latter remark, we might refer to the kidneys and the nervous system. It may be stated with confidence that, in view of the price of the book, the work of reproduction is of remarkable excellence.

It is sometimes said that it is impossible to illustrate, even approximately, all the morbid lesions which may occur. This is no doubt true, but each one engaged in routine pathological work unconsciously acquires a number of mental type-pictures, by means of which he judges of, and interprets, any pathological changes he may meet with. We do not, of course, suggest that such

⁽a) "Treatment in Diseases and Disorders of the Heart," being the Lumleian Lectures. By Sir Richard Douglas Powell, Bart., M.D., F.R.C.P. London: H. K. Lewis. Price 16s. (b) "Atlas and Essentials of Pathological Anatomy." By Professor O. Bollinger. Two Vols., crown 4to. Price 12s. 6d. each. London: Bailliere, Tindall and Cox. 1899.

works as Bollinger's "Pathological Anatomy" should supplant actual observation in the post-mortem room, but we consider that to students and others who have not such extended experience, this work will be of great service in supplying "type-pictures," and have, therefore, an important practical function.

In addition to the illustrations, which naturally constitute the most important part of the work, there is also given in the accompanying text an account of the morbid anatomy of all the systems. This—the work of an acknowledged master of this department of pathology— is succinctly and sensibly written, while his judgement on subjects which are still matters of dispute is, in our opinion, reliable, and, on the whole, correct. It is also comprehensive—in fact, we have failed to find any subject of importance omitted. There is only one point, and one of miror importance, to which exception might be taken—viz., the extensive use of classical or scholastic terms in describing lesions -as this tends in some cases to make the student regard as separate diseases what are merely one process modified by accidental circumstances. Though it is only right to state that in most cases the simple English equivalent is also given, still we think the subject would be simplified if their use were in great part discar ded.

We have great pleasure in cordially recommending the volumes to students and practitioners of medicine.

Medical Rems.

Work of the Malaria Commission.

Dr. Patrick Manson, Chief Medical Adviser to the Colonial office, stated last week that Dr. C. W. Daniels, of the Colonial Medical Service, British Guiana, who had been making investigations in India, had now arrived at Blantyre, in the Central African Protectorate, where he had joined the other members of the Commission appointed to investigate the mode of dissemination of malaria. Private letters which had reached him from Dr. Daniels, which were accompanied by specimens, confirmed the theories which had been advanced by Surgeon-Major Ross, of the Indian Medical Service, to the effect that the parasites of birds, analogous to the parasites of human malaria, were transferred by mosquitoes, which were the active agents in the propagation of malaria.

Dental Hospital of London.

In their recently issued annual report the committee of the Dental Hospital in Leicester Square draw special attention to the condition of the building fund of that institution. To place this fund in a satisfactory position they urge it is important that a sum of £3,000 should be raised for the present year, and they make an appeal to the friends of the hospital for renewed efforts to attain this object. The conveyance of the land having been settled, the Charity Commissioners have granted their order for proceeding with the work. Last year the number of operations performed was 68,298, as against 62,512 in 1897.

The Chalfont Epilepsy Colony.

THE Duke and Duchess of York will, on Thursday, June 22nd, visit Chalfont St. Peter, to open four new homes at the colony established there by the National Society for Employment of Epileptics, of which his Royal Highness is president. These homes comprise two for children, one for men, and one for cases requiring special care and treatment, and they will in the aggregate increase the existing accommodation of the colony by nearly 100 beds. The cost of building has been defrayed by special donations, given respectively by Mr. Passmore Edwards, Mr. Frederick Greene, and Mrs. Dearmer.

The Medical, Surgical, and Hygienic Exhibition.

THe annual Medical, Surgical, and Hygienic Exhibition which was held in the Queen's Hall last week was on a smaller scale than last year, several well-known caterers for the medical public being conspicuous by their absence.

in addition to many of the leading manufacturing druggists and all the principal medical publishers. Neverthe less, there were many tasteful and artistic exhibits, such as those of Messrs. Down Brothers, Messrs. Maw, Son and Thompson, the Anglo-Swiss Milk Company, Messrs. Parke, Davis, and Co., Brand and Co., Cooper and Co., and the Kronthal Water Company. During the afternoon and evenings of the four days during which the exhibi-tion was epen, the proceedings were enlivened by some excellent vocal and instrumental music, to listen to which there was usually a large gathering of ladies and gentlemen sitting in the balcony seats of the hall. Altogether about eighty-five exhibitors took part in the

THE Inebriates Acts Amendment Bill has been blocked by Mr. Pickersgill, who will oppose further progress until means have been provided for putting into operation the Inebriates Act, 1898. It is admitted on all hands that the present condition of things, in virtue whereof a person condemned to detention is set at liberty on account of the lack of accommodation, is-scandalous. The Government do not appear to be alive to the discredit attached to recent legislation by the absence of this very necessary complement of the provisions.

An Cintment Woman.

An inquest at Lambeth last week revealed to the uninitiated the existence of a female quack who practises in: the neighbourhood of Brixton. Her speciality appearsto be the preparations of ointments which are reputed to be specifies for pretty well all the ills that flesh is-heir to, from ulcers to bronchitis, and croup to whooping cough. She vaingloriously boasted of treating "thousands" of patients a week though she is only assisted by her daughter. As her ointment could not be shewn to have been in any way responsible for the death of her patient, who succumbed to tetanus, she escaped with an admonition from the coroner, but if her statements are correct the only thing she lacks, to be a successful practitioner, is a licence from the Society of Apothecaries.

PASS LISTS.

Royal College of Surgeons, Edinburgh-

The following gentlemen having passed the requisite. examinations, were, on the 16th inst., duly elected ordinary Fellows of the College :-

John Basil Hall, M.B.C.S.Eng., L.B.C.P.Lond., &c.; Charles William Donald, M.B.C.M., Edward William Scott Carmichael, M.B.C.M.; Robert Black Purves, M.B.C.M.; John Harley Gough, M.B.C.S.Eng., L.B.C.P.Lond.; Jas. Wilson McBrearty, L.B.C.S.E.; Wyndham Anstruther Milligan, M.B.C.M.; Henry John Forbes Simson, M.B.C.M., and Charles Benjamin Bossiter, L.B.C.S.E.

Royal College of Surgeons in Ireland.—Dental Examination

The following gentleman, having passed the necessary examination, has been admitted a Licentiate in Dental. Surgery of the College:—Mr. W. F. Crosse.

The following gentlemen have passed the primary that the examination that License in Dental Surgery.

part of the examinations for the Licence in Dental Surgery :- Mr. A. L. Harrison, Mr. D. L. Rogers, Mr. J. R. Small, Mr. G. M. Sterling, and Mr. G. N. Tate.

At the M.B. Examinations held during May thefollowing candidates passed :-

First Division.

Motices to Correspondents. Short Tetters, &c.

578 THE MEDICAL PRESS

CORRESPONDENTS requiring a reply in this column are particularly requested to make use of a distinctive signature or initials, and avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," &c. Much confusion will be spared by attention to this rule.

REPRINTS.—Authors of papers requiring reprints in pamphlet form after they have appeared in these columns can have them, at half the usual cost, on application to the printers before the type is broken up.

ECONOMY AD HOMINUM.

THE Listowel Guardians have refused the requisition of the medical efficers, backed by the recommendation of the Local Government Board, that competent midwives should be appointed to the districts. While excusing this refusal of help for the sick poor on the ground of economy, their next business was to pass, for the second time, a resolution in favour of free luncheons for themselves at the expense of the ratepayers, to which proposal the Local Government Board has, most properly refused its sanction.

DR. GILLES DE LA TOURETTE'S Clinical Lecture on "Convulsive Twitching" has been received from our French correspondent.

THE SABBATARIAN MONOMANIAC.

THE SABBATARIAN MONOMANIAC.

THE "Lord's Day" Society sued, last week, at the Stoke Sessions no less than eleven shopkeepers for the offence of Sunday trading. The trading consisted in putting some drops in aching teeth, which seem to be frequent about that neighbourhood. The Magistrate fined the delinquents one farthing each. If he could have sent the prosecutors for a couple of hours to the stocks it would be what they deserved.

Dr. H.- The correspondence is far too voluminous for us to be able to deal with it as you suggest. Moreover, the matter is one that cells for investigation at the hands of disinterested persons in a position to gauge the merits. We shall not lose sight of your contention.

K. B.—We thank you for the newspaper cutting. De minimis non curst lex. There is, however, a principle involved, and this, directed of its provincial appurtenances, we shall discuss at the first opportunity.

A LUCID EXPLANATION.

A PROVINCIAL visitor to Lills on the occasion of the opening of the Pasteur Institute in that town, expressed surprise that the Ministers of Agriculture and of the Colonies should have been chosen to preside over the function. It was pointed out to him that they were obviously the 'most appropriate officers of the State in this connection, seeing that the work of the Institute was so largely concerned with "cultures" and "colonies."

Dr. J. H.—Good or bad the Notification Act is law, and it is our duty to give it our support. Its administration may sometimes challenge criticism, but the principle of notification, has, we imagine, passed beyond the stage of adverse comment. We have, therefore, referred your communication to the W. P. B.

Meetings of the Societies and Tectures.

TRURSDAY, JUNE 18T.

British Balffological and Climatological Society (20 Hanover Square, W.).—3.30 p.m. General Meeting. Election of Officers and Council for the year 1899. 4 p.m. Ordinary Meeting. Dr. I. Murray: Scarborough as a Health Resort in Phthisis.—Dr. Shirley-Jones: Treatment of Neuralgia by the Droitwich Brine Baths.

CENTRAL LONDON THROAT, NOSE, AND EAR HOSPITAL (Gray's Inn Road, W.C.).—5 p.m. Dr. D. Grant: Diagnosis and Treatment of Nerve Deafness.

FRIDAY, JUNE 2ND.

CHILDHOOD SOCIETY (Library of the Sanitary Institute, 72, Margaret Street, W.). - 5 p.m. Discussion on the Education of Children Feebly Gifted Mentally under the Care of Guardians (opened by Dr. G. E. Shuttleworth).

WEST LOSDON MEDICO-CHIRURGICAL SOCIETY (West London Hospital, Hammersmith, W.).—8.30 p.m. Clinical Evening. Cases will be shown by Mr. C. B. Keetley, Dr. L. Dobson, Mr. R. Lake, Mr. L. A. Bidwell, Mr. McAdam Eccles, and others.

LARYWGOLOGICAL SOCIETY OF LONDON (20 Hanover Square, W.).—5 p.m. Cases and Specimens will be shown by Dr. Permewan, Dr. St. Clair Thomson, Dr. J. Horne, Dr. S. Spicer, Dr. H. Tilley, Dr. W. Hill, Mr. de Santi, Mr. R. Lake, and others.

Monday, June 5th.

and washing. Applications to the Clerk, Queen's Chambers, Cardiff.

Harris Parish Council.—Medical Officer and Public Vaccinator for the Southern Division. Salary 290; other emoluments. Applications to Mr. Thos. Wilson, Solicitor, Lochmaddy, N.B.

Holloway Sanatorium.—Virginia Water.—Senior Assistant Medical Officer Salary commencing at 2300 per annum, with board, lodging, and washing.

Metropolitan Asylums Board.—Assistant Medical Officer at the South-Eastern Fever Hospital, New Croes, S.E. Salary commencing at £160, with board, lodging, attendance, and washing. Applications to the Clerk to the Board, Norfolk Street, Strand. School Board for London.—Medical Officer for the training-ship Shattesbury, lying off Grays, Essex. Commencing salary £100 a year. Applications to the Clerk, School Board Offices, Victoria Embankment, London.

Staffordshire General Infirmary, Stafford. House Surgeon. Salary £100 per annum, with board, lodging, and washing.

West Norfolk and Lynn Hospital, King's Lynn.—House Surgeon. Salary commencing at £20 per annum, with board, &c.

West Riding Asylum, Waksfald.—Fourth Assistant Medical Officer. Salary commencing at £210 per annum, with board, &c.

West Riding Asylum, Wakefield.—Fourth Assistant Medical Officer.
Salary commencing at £100 per annum, with furnished apartments, board, washing, and attendance.

Appointments.

Byford, W. F., L.B.C.P.Lond., M.R.C.S., Medical Officer for the No. 1 Sanitary District at the Buthin Union.

Crowley, Ralph, H., M. D.Lond., M.R.C.P., M.R.C.S., Workhouse Medical Officer and Visiting Physician to the Hospital, by the Bradford Board of Guardiaus.

Dave, S., M.R.C.S., L.R.C.P., D.P.H.Lond., Medical Officer of Health to the Urban District Council of Caterham.

Fratherstone, G. W. B., L.R.C.P., Lond., M.R.C.S., Medical Officer for the Badnorshire Sanitary District of the Hay Union.

Godwin, F. J., M.R.C.S., L.R.C.P., House Surgeon to the Infirmary; Burton-on-Trent.

Hawkins-Ambler, G. A., F.R.C.S.Edin., Assistant-Surgeon to the Liverpool Stanley Hospital.

Jacrson, Thos., M.D.Edin., M.R.C.S., Medical Officer for the First Division of the Greystoke Sanitary District, Penrith Union.

Kirkpatrick, T. Percy C., M.D., Americation Officer at the Infirmary, Parish of St. Marylebone, London.

Mathew, C. P., L.R.C.P.Lond., M.R.C.S., Medical Officer for the Tregony Sanitary District of the Truro Union.

Read, B. T., L.R.C.P.Lond., M.R.C.S., Medical Officer for the Odiham Sanitary District of the Hartley Wintney Union.

Read, B. T., L.R.C.P.Lond., M.R.C.S., Medical Officer for the Bilton Sanitary District of the Warmley Out relief Union.

Todd. S., L.R.C.P.Lond. M.R.C.S., Medical Officer for the Bilton Sanitary District of the Warmley Out relief Union.

Todd. O., L.R.C.P.Edin., M.R.C.S., Medical Officer for the Bilton Sanitary District of the Warmley Out relief Union.

Ward Edward, M.B., B.C., M.R.C.S., Professor of Surgery in the Yorkshire College Department of Medicine.

Yonge, Eugene S., M.D., Honorary Assistant Physician to the Manchester Hospital for Consumption and Diseases of the Throat.

Births.

MURRAY.—On May 24th, at 110, Harley Street, London, the wife of John Murray, F.R.C.S., of a son.
Scorr.—On May 25th. at 3. Southgate Road, Winchester, the wife of T. W. Scott, M.B., of a son.

Marriages.

MITCHELL—NICKELS.—On May 20th, at Christ Church, Woburn Square, Bloomsbury, London, James E. H. Mitchell, M.R.C.S. (Eng.), L.B.C.P. (Lond), &c., of Middlewich, youngest son of the late Timothy Mitchell, of Eightlands, Dewsbury, to Maria Lois, youngest daughter of the late Samuel Nickels, of Sunderland, and formerly of Fowey.

Beaths.

ASKWITH.—On May 27th, at the Vicarage, Taunton, Marion, widow of Robert Askwith, M.D., late of Cheltenham, aged 75.

BATEMAN.—On May 19th, at Albion Park, New South Wales, Arthur Wigley Bateman, H.A.Oxon, L.R.C.P, and L.R.C.S. Edin., of Kibworth, Leicestershire, aged 34.

MILLER.—On May 24th, at Bath, Harriet, widow of the late A. R. Miller, M.D., M.R.C.P. Edin., daughter of the late Wm. Morgan, of Ravensdale, Kildare.

MACKEZIE.—On May 17th, suddenly, John William Harris Mackenzie, M.R.C.S., at Daisy Bank, Cheadle, Staffordshire, aged 75. aged 75.

M.R.C.S., late of Bradford, Yorkshire, aged 66 years.

3 M.D.'s

and

Sunlight Soap

One States—"The points in the composition of this soap that are the most valuable are its freedom from free alkali, the large percentage of fatty acids it contains, and the PURITY of the materials employed in its preparation."

- A Second States—"I have tested it by applying it repeatedly to the skin of a patient who has for years been subject to eczema of a severe type. . . . The application excited no irritation whatever."
- A Third States—"I can conscientiously say that I never used a pleasanter or more cleanly soap than your SUNLIGHT SOAP. I now use nothing else in my household."

Medical Testimony

therefore establishes the fact that SUNLIGHT SOAP

- I—Is free from free alkali;
- 2-Contains a large percentage of fatty acids;
- 3-Is made of pure materials;
- 4-Does not irritate the skin;
- 5-Is pleasant and clean.

LEVER BROTHERS LIMITED, Soapmakers to the Queen.

Severe cases of Gastric Pain, Distress after Eating, Nausea and Vomiting relieved and permanently benefited by

SCHACHT'S SEDATIVE BISMUTH

(LIQ. BISMUTHI SEDATIVUS, SCHACHT).

The tendency of modern medical practice is to give less and less physic. Yet good drugs, skilfully compounded, enable our physicians to accomplish much that former practitioners were powerless to effect with the cruder means at their disposal. Witness the following:—

"GENTLEMEN,

" December 22, 1891.

"I write to tell you of the very pleasing success that I have obtained through the use of Liq. Bismuthi Sedativus. One lady patient, who (I quote her own words) had been treated before she applied to me by three medical men with all sorts of physic, stated that for two years she had not had one day without pain, nausea or vomiting, and derived little benefit from any medicine until I ordered for her this preparation of yours. Since the first time of administration the vomiting ceased, and the pain and nausea gradually became less, until now she feels perfectly well. I shall continue to prescribe this valuable remedy in all suitable cases.

"Yours faithfully,

_____, M.D.

Another report :-

"The Liq. Bismuthi Sedativus was prescribed in water to a patient suffering from alcoholic inflammation of the stomach, who had to be fed by nutritive enemata, and on whose stomach nothing would rest, not even a fairly large dose of hydrocyanic acid. The stomach was painful on pressure, and the nutritive enemata did not seem to be benefiting the case, and were very disagreeable to her. A small teaspoonful of Schacht's Mixture was given with a table-spoonful of water, and it was retained; the dose was repeated every three hours, and the patient declared the pain and irritation of the stomach to be much relieved. A milk diet was now cautiously commenced, and in two days the patient could take corn-flour and such-like diet. Two other cases similar in character, but not so severe, were also quickly relieved by the preparation."

Other members of the profession write in similar grateful terms. This is no secret remedy, but a combination of Schacht's Pepsina Liquida (a really perfect pepsine) with Schacht's Bismuth and Sedatives. The formula is given on each label.

Dose-i to 1 drachm diluted.

In 4-oz., 1-lb., and 1-lb. Bottles.

To be obtained of all the Wholesale Houses; or direct from

"DEAR SIRS,-

"I have used your preparation 'Nepenthe' for a number of years in cases of insomnia connected with insanity, and have always found it above all other anodynes the 'King of Narcotics.' I don't think I should be doing you justice if I did not report to you on its marvellous efficacy. I have found it always produce hours of peaceful sleep, and to be unattended by any bad results. Patients suffering from melancholia with accompanying insomnia under my care have taken it every night for years without one bad symptom. I never find thirst, dryness of the tongue, or constipation, result from its use, and I view it as the most valuable remedy we possess for allaying brain irritation, and producing peaceful and healthy sleep. I have thoroughly tested all the various remedies usually given for the relief of some of the troublesome phases of mental disease, and can safely say that none are so good or reliable as 'Nepenthe.' It has all the good properties of opium without any of its drawbacks.

"I am, dear Sirs,

"Yours truly,

HEY'S INTERNAL DERANGEMENT OF THE KNEE-JOINT. (a)

By JOHN KNOTT, M.D., Ch.B. (Univ. Dub.)

In the volume of "Practical Observations in Surgery," published by Mr. Hey, of Leeds, is included a paper "On Internal Derangement of the Knee-joint," which contains the original description of the very peculiar lesion to which the name of this distinguished surgeon has since been attached. It is given in the following words:—"This joint is not unfrequently attended with an internal derangement of its component parts, and that sometimes in consequence of trifling accidents. The disease is, indeed, now and then removed, as suddenly as it is produced, by the natural motions of the joint without surgical assistance; but it may remain for weeks or months, and will then become a serious misfortune, as it causes a considerable degree of lameness. . . . This disorder may happen with or without contusion. former the symptoms are equivocal till the effects of the contusion are removed. When no contusion has happened, or the effects of it are removed the joint with respect to its shape, appears to be uninjured. If there is any difference from its usual appearance, it is that the ligament of the patella appears more re-laxed than in the sound limb. The leg is readily bent or extended by the hands of the surgeon, and without pain to the patient; at most the degree of uneasiness caused by this flexion or extension is trifling. But the patient himself cannot freely bend nor perfectly extend the limb in walking; he is compelled to walk with an invariable and small degree of flexion. Though the patient is obliged to keep the leg thus stiff in walking, yet in sitting down the affected joint will move like the other.

"The complaint which I have described may be

"The complaint which I have described may be brought on, I apprehend, by any such alteration in the state of the joint as will prevent the condyles of the os femoris from moving truly in the hollow formed by the semilunar cartilages and articular depressions of the tibia. An unequal tension of the lateral or cross ligaments of the joint, or some slight derangement of the semilunar cartilages may probably be sufficient to bring on the complaint. When the disorder is the effect of contusion, it is most likely that the lateral ligament on one side of the joint may be rendered somewhat more rigid than usual, and hereby prevent that equable motion of the condyles of the os femoris which is necessary for walking with firmness."

Such are the words of the earliest notice of this peculiar lesion which we possess, and such is the uncertainty as to the accurate diagnosis in which the original describer has left his readers, and, so far as we can see, was obliged to remain himself.

Sir Benjamin Brodie notices Hey's observations, and says that "the symptoms very much resemble those produced by a loose cartilage within the joint," but his views of the actual nature of the existing condition seem even more indefinite than those of

(a) Read in the Surgical Section of the Royal Academy of Medicine in Ireland, April 7th, 1899.

the latter writer; and he states further on, in reference to a case which had occurred in his own practice, that "the facts which I am about to state are not very easy to be reconciled, either with this hypothesis or with that successed by Mr. Hay."

or with that suggested by Mr. Hey."

When a very junior surgeon I ventured to publish my views on this obscure affection. They were based upon personal experience of symptoms and signs, and on careful anatomical investigation. The lapse of time has but served to confirm them, and as they do not seem to have indoctrinated the present generation of surgical authorities so completely as I could have wished, I have determined to submit them once more to the examination of my professional brethren. Many, at least, of the surgical apostles of the present day appear to have made up their minds to a very decided view of the actual state of things in Hey's internal derangement of the knee-joint; and, without much more conclusive evidence to go upon than that which was then possessed by the distin-guished surgeons whose names I have mentioned, unhesitatingly inform their readers or hearers, as the case may be, that the symptoms are due to a luxation of one of the semilunar fibro-cartilages which are interposed between the cartilaginous surfaces in the femore tibial articulation.

Before proceeding further with my subject I will mention that I understand by the term Hey's Internal Derangement of the Knee-Joint, an abnormal condition suddenly resulting from the application of external violence, and as suddenly reducible by appropriate manipulation.

In the tenth edition of Erichsen's "Surgery," edited by Messrs. Marcus Beck and Raymond Johnson, will be found the words of this high authority thus written:—

"Subluxation of the Knee, Displacement of a Semilunar Cartilage, or, as it was termed by Hey, internal derangement of the knee-joint, is a common and very troublesome accident. It usually occurs whilst the knee is slightly flexed and the leg rotated inwards or outwards. Instances of the causation are given:—"Rising from a kneeling position, or kicking a football (the limb affected being that upon which the patient is standing), or by striking the toe against a stone in walking.

"In many cases a distinct fulness can be recognised on one side of the ligamentum patellæ in the hollow between the tibia and the femur, and there is tenderness at the same spot. In the course of a short time, in most cases, the joint becomes distended by inflammatory effusion.

"This accident has been the subject of much investigation since it was first described by Hey. It has long been recognised that it is due to a displacement of one of the semilurar cartilages."

ment of one of the semilunar cartilages."

In the "System of Surgery," edited by Mr. Treves, p. 1015 of Vol. I. has the running title of "Displacement of Semi-lunar Cartilage," calling attention to a section the opening of which on this page bears the title, "Subluxation of the Knee, Internal Derangement of the Knee, Dislocation of the Semilunar Cartilage." The writer (Mr. A. Marmaduke Shields) proceeds to inform us that: "Under this heading is described a peculiar condition of the knee-joint, which almost invariably is associated with a wrench,

sprain, or other injury, and which is characterised by a sudden sensation of the joint being "put out"; some fixation and impediment to the movements of the limb, more or less pain, and, lastly, by the functions of the articulation being suddenly and

swinging the body to make a stroke at golf, or in the rotation which occurs in stepping out of a dogcart. (Treves.) "In practice, the internal cartilage will be found to be most generally displaced. This occurs in violent external rotation, principally performed by the biceps. . . . The gap between the internal condyle and the tibia is, however, increased, and the movable internal cartilage is apt to slip between the internal condyle and the inner tuberosity of the tibia. . . . Godlee has argued from anatomical considerations that the external cartilage is more frequently displaced. Clinical experience points, however, undoubtedly to the greater frequency of the displacement of the internal

When a student engaged in preparing for my first surgical examination, it was considered very necessary for every candidate to know the special views of one member of the board before which we, unfledged aspirants were obliged to present ourselves. His explanation of the greater frequency of "derangement" of the internal cartilage was its intimate adhesion to the corresponding lateral ligament, by which it was dragged out of its position when the leg was wrenched outward with sufficient force. How the cartilage in question could be so dragged out of the joint without having its cornual attachments

torn remained the meta-physical part of the problem. Mr. Herbert W. Allingham in his exhaustive monograph on "Internal Derangements of the Knee-joint," gives the following account of displacement of the semilunar fibro-cartilages:—

"When rotation outwards takes place, the gap between the internal condyle of the femur and the head of the tibia will be found to be increased; and the internal semilunar cartilage is more movable, and consequently is apt to slip too far in between the condyle of the femur and the corresponding head of the tibia.

"A parallel state of affairs results when the tibia is rotated inwards, for then the gap between the external femoral condyle and the head of the tibia is increased, and then the external cartilage is more

movable.

"When the knee is flexed, the anterior part of the internal semilunar cartilage glides backwards on the head of the tibia; if the leg be then notated outwards, the internal semilunar cartilage will be drawn in between the internal condyle of the femur and the head of the tibia. Sudden movement of extension will then cause the internal condyle to roll on to too much of the internal semilunar cartilage. Now, as extension is always combined with external rotation of the tibia, the inner tuberosities of the latter must make a sweeping movement forwards and outwards. The internal cartilage will be held by the femoral condyle, and as the tibia makes its curve forwards and outwards the coronary ligaments will be stretched, or even torn. This, doubtless, is what occurs in aggravated cases, and when the accident has recurred frequently. The converse applies to displacements of the external semilunar cartilage. In the milder forms there may be only a stretching and relaxed condition of the coronary ligaments, but when once thus relaxed they are always in danger of being further stretched or even ruptured.

"There are some conditions which predispose to these derangements.

"A lax condition of the ligaments about the joint caused by general debility or previous synovitis, predisposes to these accidents on account of the insecure way in which the femur and tibia are then bound together. Prolonged flexion of the knee-joint, as in kneeling, strains the anterior part of the coronary ligaments, and renders possible a liability to these disorders.

Our courteous secretary, Mr. John Lentaigne, called my attention to the October issue of the Annals of Surgery, in which there is an elaborate paper on the "Cause and Treatment of the Subluxation of the Semilunar Cartilages of the Knee-joint." by Newton M. Shaffer, M.D., in which the author believes that

"(1) In many cases of Hey's joint there is an acquired or, perhaps, congenital lateral mobility of the knee-joint. This condition existing, the normal rotation of the tibia in flexion or extension of the

knee is greatly increased.

"(2) In many cases, if not in all cases, there exists an elongated ligamentum patellæ, which so modifies the action of the quadriceps extensor muscle upon the tibia that the force of its contraction upon the tibia is modified or delayed in such a way that extension and rotation are not synchronously performed. And it seems more than probable that this condition forms an important factor in the production of the subluxation of the semilunar cartilage."

And again, the author quotes Allingham's state-

ments: "The injury is caused by some sudden and almost involuntary movement. Most of the muscles governing the joint are then thrown off their guard,

or fail to act in concert one with the other.

Dr. Shaffer then proceeds to say: "But I do not agree with Mr. Allingham when he says 'All this may occur even in a healthy joint,' if for healthy we substitute 'normal,' except under circumstances where great lateral pressure is applied, and when a true subluxation of the tibia occurs as a result of direct violence. In these cases there existed a condition which I have attempted to describe, and which directly favoured the subluxation. And further, the muscles are not 'off their guard.' The quadriceps acts promptly; but the patella, instead of clamping the femur with a normal length of ligament in the trochlea, is tilted upward at the lower end, and the muscular effort is so delayed that the movable semi-lunar cartilage is caught, perhaps only slightly pinched, or really dislocated, and sometimes seriously damaged.

In nearly all the above quoted descriptions of this lesion there appears to be a tacit assumption that one of the semilunar fibro-cartilages has been displaced. Too intimately associated with this unproved assumption is a positively inexplicable haziness in the minds of the respective writers regarding the actual struc-

ture of the knee-joint.

To examine the validity of the grounds for such a conclusion is my chief object in making this com-munication. To do so satisfactorily it will be necessary to call attention to some of the more prominent features in the mechanism of the knee-joint, and to notice more especially the connections of the fibrocartilages, which concern us so intimately in this lesion.

The upper end of the tibia presents an extensive surface, bearing two articular facets separated by a rough non-cartilaginous interval, which runs in an antero-posterior direction, and is chiefly destined for ligamentous attachment. Of these facets the internal is the larger and of somewhat oval shape, with the long axis passing from before backwards; it is also somewhat more hollow than the other, although the

amount of depression on either side is but slight, and, in the recent state, is still further diminished by the greater thickness of the articular cartilage in the central part. The outer facet approaches the circular

The inferior extremity of the femur presents two articular facets which are, respectively, more extensive than the corresponding ones on the head of the tibia on which they rest. The deep intercondyloid notch separates the two condyles, of which the internal is prolonged downwards considerably further than the external—a disposition of parts which determines the internal obliquity of the shaft of the femur, and the formation of an angle salient inwards at the inner aspect of the knee-joint.

It is obvious that the very shallow depressions on the upper end of the tibia can afford no security for the condyles of the femur during the various movements of the joint. The glenoid cavities for the reception of these articular prominences are, accordingly, almost solely formed by the semilunar cartilages. Each of the latter structures presents three surfaces—a superior, which is markedly concave; an inferior, nearly flat; and an external, forming the prominent rim, which is connected with the fibrous structures surrounding the joint. This rim, in a well formed adult knee, is of considerable thickness.

At the inner (concave) side the cartilage thins down to an irregularly festooned edge. On examination of the mutual relation of these fibro-cartilages, we find that the external forms almost a complete circle, while the internal forms a C-shaped curve, elongated from before backwards, and of which the extremities embrace those of the outer cartilage. These extremities (cornua) are extremely strong, and bind the cartilages with great firmness to the non-articular portions of the osseous surface, while the circumferential aspects of the cartilages are bound—rather looselyto the corresponding margins of the head of the tibia by the so-called "coronary" ligaments. The other surfaces are covered with synovial membrane, and glide smoothly—the upper on the cartilaginous surface of the corresponding femoral condyle, the lower on the head of the tibia. "The fore part of each is less fixed than the hinder, so that it may be free to follow up the condyles as the latter recede from the front of the tibia in flexion, and be pressed back again into its place in extension" (Humphry). In the case of the external cartilage the posterior cornu has an accessory attachment to the femur, which accompanies the posterior crucial ligament (cornu postici adhæsio primo of Weitbrecht, ligamentum cruciatum tertium of Robert. This femoral adhesion causes the cartilage to follow, in a limited degree, the movements of the lower end of the thigh bone; and its nearly circular outline, with the greater looseness of its coronary attachments, and the fact that it does not, like the internal semilunar fibro-cartilage, adhere intimately to the corresponding lateral ligament of the joint, all combine to give to the external of these cartilages a greater degree of mobility than is permitted to the internal.

The more obvious movements of the knee-joint are those of flexion and extension—characteristic of the ginglymus articulation, of which it forms an imper-fect type. In addition to these, the knee possesses, when moderately flexed, a rotatory movement, which, as shown by the brothers Weber, may attain a range of 39 degs. in the normal joint. The vertical axis around which these movements take place passes through the head of tibin at the inner side of the spine. The use of the greater mobility of the outer cartilage is obvious in this condition; for if it were absolutely fixed to the head of the tibia, any considerable rotatory movement of the latter

condyle out of its articular cavity. Slight lateral movements of the passive variety may also be demonstrated in the knee-joint when the leg is semi-flexed. In this position, the ligaments being relaxed, external pressure will produce movement of the tibia to either side; the latter bone gliding, to a very limited extent, of course, upon the articular facets of the femoral condyles.

With regard to the more ordinary movements of the knee, an interesting anatomical fact has been demonstrated by Tillaux. This anatomist pointed out that a vertical antero-posterior section through one of the condyles is not limited at the lower end by an arc of a circle, as formerly represented; the cartilaginous surface represents two arcs-one anterior and the other posterior, belonging to circles of different radii, and separated by a portion of a very flattened ellipse. The mechanical result of this arrangement is that in flexion of the knee there is, at first, rotation round an anterior axis; towards the middle of the movement, a combination of rotation and gliding; which is, in turn, replaced by a purely rotating movement towards the end of the act of flexion. The axis, around which the movements of flexion and extension take place, passes through the femoral condyles at the level of the attachment of the lateral ligaments of the joint.

An even moderately careful scrutiny of the re-corded observations of "internal derangement of the knee-joint" will show that the writers on this subject have included, under the same denomination, two distinct varieties of surgical lesion—one in which the displacement is supposed to have affected the semilunar cartilage only; the other in which, besides the "derangement" of the cartilage there is also a change established in the normal relations of the articular surfaces of the femur and tibia; or, in other words, an incomplete dislocation of the leg.

Some cases of the former class would appear to have been unaccompanied by prominences or any other outward and visible sign of the existing internal derangement. This would appear to have been pretty much the case in some of the instances observed. by Hey himself. A good case of the typical "internal derangement" has been recorded by Bonnet (de Lyon): "A very active man, at. 45, twisted his knee in making a movement of external rotation. I saw him two days after the accident; no physical derangement could be detected in the knee; there was merely a small amount of serous effusion into the synovial cavity. The patient could walk only with extreme pain, he suffered much, and could extend his leg upon the thigh but in a very incomplete manner. This disproportion between the impairment of motion, which was carried to an extreme degree, and the inflammation, which was but slight, made me think that a luxation of the semilunar cartilage had probably taken place. I then flexed the knee as much as possible; this flexion was painful. Having done this a first time I extended the leg, and flexed again. This manœuvre was followed by immediate relief; the patient was able to walk with less pain, and to extend the leg upon the thigh completely. The inflammation rapidly subsided."

Very valuable evidence with regard to the nature

and mechanism of this lesion was obtained by the same surgeon from the results of experiments performed on the dead body. On the cadaver of an adult male who had succumbed to a chronic malady, Bonnet found that by flexing the leg to form a right angle with the thigh, as the body lay in the prone position, and suddenly rotating the foot outwards, a peculiar snap was felt, after which the limb remained in the position of external rotation, with the leg flexed bone would inevitably throw the external femoral upon the thigh at an angle of about 45 degs. At the

antero-internal aspect of the knee-joint a prominence could be felt corresponding to the inner tuberosity of the tibia; this prominence projected in front of the inner condyle of the femur; the head of the femur was carried backwards and inwards. The rotation of the leg, measured by the deviation of the foot, amounted to nearly a quarter of a circle. Upon extending the leg (for which a slight effort was found necessary) the snapping sensation was again felt, and the normal relation of the articular surfaces was reestablished. Subsequent dissection of the knee showed no displacement of the inter-articular structures, and no appreciable laceration of either ligament or muscles. In the next experiment he removed the patella; and, repeating the movements already described, he watched the effect on the inter-articular structures. The snapping sensation was then found to be produced by the passage of the inner condyle of the femur behind the semilunar cartilage, which was, accordingly, pushed forwards on the internal glenoid cavity of the tibia, but without any laceration of the internal lateral, or capsular ligament of the joint. On the outer side, the condyle had undergone no considerable displacement; it was carried a little forwards from its normal position, but still lay in the glenoid cavity formed by the external semilunar cartilage. On extension of the limb, with a little effort, this peculiar disarrangement was at once rectified. The experiment was frequently repeated, and always with similar results.

THE MEDICAL PRESS.

Cases have been observed in the living body which correspond very closely indeed with the facts above recorded as observed by Bonnet on the cadaver. But none of these "derangements" can properly be regarded as a luxation of the semilunar cartilage; they are incomplete rotatory dislocations of the leg

The possibility of such a displacement cannot be doubted by those who are familiar with the normal internal arrangement of the structures of the knee-joint, and the author of the present communication can add to the evidence already published on this subject a description of the accident as it has repeatedly occurred in his own person.

(To be continued.)

Baris Clinical Tectures.

INTOXICATION THE OF ADDISON'S DISEASE.

DELIVERED AT THE LAENNEC HOSPITAL.

By Dr. CHAUFFARD,

Professor Agrege at the Medical Faculty of Paris; Physician to the Paris Hospitals.

THE theory of Addison's disease, still a matter of controversy, is based on two fundamental principles. One, the result of clinical observation and due to Addison, is the existence of a special cachexy, accompanied by profound asthenia and pigmentation of the skin and mucous membranes, and characterised by more or less degeneration of the suprarenal cap-sules. The other, deduced from experiments and formulated by Browning, that the suprarenal cap-sules form an organ indispensable to life, the total loss whereof is rapidly followed by death.

The problem, thus clearly defined, seemed on the way to a satisfactory solution, when the new nervous theory was brought forward, according to which the cause of the affection is to be sought in a lesion of the abdominal portion of the sympathetic nervous system and the solar plexus. Addison's disease may

be induced, it is asserted, not only by lesions of the pericapsular sympathetic system, but also by lesions of the solar plexus, as in the case reported by Raymond, where generalised lymphadenoma was found to exist in association with integrity of the suprarenal capsules and sclerosis of the solar plexus, comprising the whole ganglionic mass. The same is true with regard to lesions of the semilunar ganglia, as is shown by a case of Brault and Perruchet's, in which a tuberculous mass was found attached to the right semilunar ganglion, without apparent lesion of the

The partisans of the suprarenal theory replied by a new and remarkable series of experimental researches, having for object to strengthen and confirm clinical experience. These experiments, carefully carried out and studied, proved conclusively that animals deprived of the suprarenal bodies die from poisoning, and that their blood shows a special and peculiar toxicity. Moreover, the preservation of a small portion of the suprarenal parenchyma suffices to neutralise the

intoxication, and insures their survival.

These toxins, due to suprarenal inadequacy, exist, however, not only in the blood, but also in the muscles, whence they may be extracted by means of alcohol, and they are physiologically identical with the toxic substances elaborated in the muscles of an animal in normal condition, when subjected to an excessive amount of work. An animal without adrenals, at the least exertion, shows signs of rapid and persistent fatigue, which does not disappear even after a long period of rest.

Finally, the paralysis which attacks animals whose suprarenal capsules have been removed appears to be principally due to changes affecting the terminations of the motor nerves, the muscles themselves being but slightly interfered with. We have, therefore, to do with a veritable curare-poison. This is a point of great importance, seeing that the experimental proof of the antitoxic action of the suprarenal capsules on the waste-matter of muscular disassimilation furnishes the explanation of one of the fundamental symptoms of the bronzed cachexy, the so-called Addisonian asthenia.

These experiments, however, only prove two things, viz, the rapid auto-intoxication of the organism after destruction of the suprarenal glands, and the curarelike nature of the toxin thus produced or retained for want of elimination. Neither the pigmentation of the skin and mucous membranes nor the characteristic gastric troubles of Addison's disease have ever

been reproduced by experimentation.

That, however, is not to be wondered at, seeing that ablation of the suprarenal capsules is of necessity a coarse measure, too sweeping in its effects and incapable of the delicate physiological disassociation that characterises the lesions produced in a slow and progressive manner by Addison's disease. The symptoms as a whole certainly point to an intoxica-Two cases which have recently come under my observation seem to me very significant in this

respect.
One of these was an Italian, fifty years of age, whom some of you doubtless saw in my ward at the Broussais Hospital on two separate occasions. He is a typical specimen of Addisonian cachexy, without other morbid antecedents than a slight attack of occupation lead poisoning. A year ago he developed a sudden and persistent distaste for foods of all kinds, accompanied by vomiting of alimentary or bilious matter. He had lost both weight and strength. He complained of pain in the lumbar, abdominal, and epigastric regions; the characteristic pigmentation had invaded the labial, lingual, and bucco-genial mucous membranes, as well as the integuments covering the face nipples, gluteal furrow, scrotum and penis, front of the patella, and dorsal aspect of both

hands. The only visceral lesion was a slight degree of induration of the apex of the left lung. The urine was normal. Twice this man was admitted to the hospital in a very prostrate condition, suffering from a fully developed crisis of gastric intolerance and throwing up what little he was able to swallow. both occasions these distressing symptoms subsided rapidly with no other treatment than rest, and our man was anxious to leave, in the belief that he was cured of his ailments and able to resume work. Could there be a more striking example of progressive auto-intoxication under the influence of muscular fatigue and bad hygienic conditions, showing a constant tendency to disappear in the early stage of the disease, as soon as the necessary repose has permitted the elimination of the accumulated toxin?

The second case, from my private practice, exemplifies very well the rapidly fatal course sometimes following Addison's disease. A lady, et. 35, of strumous diathesis and delicate from childhood, was said to have suffered for several years from nausea and attacks of retching, resulting in the ejection of a little frothy or viscid matter. In December, 1892, she consulted one of our most celebrated dermatologists, with whom she had been acquainted for a long time; but a thorough examination revealed no trace or any special pigmentation. She passed the winter at Cannes, where she began to rapidly lose flesh, and, with the gradual disappearance of her strength her skin began to change colour and became pigmented. She ultimately developed complete and obstinate anorexia.

Late in February, 1893, she returned to Paris, and came to consult me. I found typical Addisonian pigmentation, with the usual series of localisations on the mucous membranes of the mouth, tips of the breasts, integuments of the face, and uncovered portions of the body, patellar regions, and nails. The face was thin and hollow, the eyes sunken, with black rings; the expression was drawn and suffering, indicating complete exhaustion of the vital force. There was no pain but the appetite was completely lost. Motion of any kind produced nausea; rising, taking a few steps, or making a slight exertion were sufficient to induce angor, extreme malaise, and exhausting retching.

I decided to try hypodermic injections of supra-renal juice, but little or no benefit resulted to the patient from these injections. The patient dragged on until April 7th, when death finally ensued, the vital energy slowly fading away without being affected either by injections of ether or caffeine, or The toxin of by nutritive or aqueous enemata. Addison's disease, in this case, not only exhibited all the characteristics of curare, but acted also as a poison to the myocardium and the cardiac terminations of the pneumogastric nerves, producing paralytic tachycardia.

The idea of the all-important role of auto-intoxication in Addison's disease must not be pushed too far, and it cannot be invoked in explanation of, or as furnishing sufficient cause for, all the symptomatic phenomena. Though I firmly believe in its existence in this disease, I also believe that it alone is not at the bottom of all the lesions; and the most prominent link, from a clinical point of view, in the symptomatological chain, the pigmentation of the skin and mucous membranes, is assuredly not of toxic nature. In this connection Alexais and Arnaud's researches and discoveries are to be appreciated at their full value, showing us, as they do, that the suprarenal lesions alone are not capable of producing melanoderma. Something more is needed for this, namely, the participation in the morbid process of the periglandular capsule, and particularly of the small sympathetic nerve-ganglia comprised is the

fibrous structure of the latter. And, moreover, it must be remembered that this part of the sympathetic apparatus is far from being the only one, the morbid condition of which may influence the chromatogenous action of the skin. The experiments of Raymond and of Brault and Perruchet show clearly that any irritating, and sufficiently intense, lesion of the solar plexus or semi-lunar ganglia may result in pigmentation of the skin and mucous membranes.

The physiological mechanism of this process is as yet rather difficult to determine. Raymond has advanced an ingenious theory, according to which the human skin normally contains feebly pigmentary elements, subject in a certain measure to nervous influence in the same manner as the chromatoblasts of certain animals are under the immediate direction of a special innervation. The Addisonian pigmentation is then due to dystrophic disturbance in the chromatogenous apparatus of the skin, depending upon an irritative lesion of the peri-suprarenal or semi-lunar ganglia, or of the solar plexus.

Be that as it may, we are constrained to consider Addison's disease as a syndroma implying, in typical cases, a double lesion: the almost total destruction of the suprarenal glands, and irritation, by compression or sclerosis, of the neighbouring sympathetic ganglia. As a rule, the extension of a caseous infiltration of the capsules is liable to produce both these lesions. At the same time, either of them may exist

alone, a circumstance which explains the occurrence of double capsular tuberculosis without accompanying melanoderma, and inversely, sympathetic lesions and melanoderma without degeneration, of the

It is this idea which I think must henceforth be our guide in clinical and anatomical researches, so as to distinctly separate, in the symptomatology of the disease, all that is directly due to the glandular lesion from that which merely points to accessory implication of the sympathetic system, and to distinguish the complete symptomatic manifestation of Addison's disease from abortive and atypical cases, in which only one of the pathogenetic processes is at work.

To attempt to explain in this way all the abnormal cases already published would undoubtedly be a difficult undertaking; but it must be remembered that the reports are not conceived in a catholic spirit, and that each author has been bent upon explaining his particular case in accordance with the pathogenetic theory, to which he gives his preference. And it is evident that neither the nervous theory, nor the theory of capsular insufficiency alone is able to explain all the cases recorded without straining the facts. The negative cases, and the so-called contradictory symptoms, only prove the narrowness and inadequacy of our pathogenetic conceptions. The two theories actually discussed are not at all incompatible; on the contrary, they mutually complete each other. To determine the exact relationship existing between the symptoms of a toxic nature and those of sympathetic origin seems to me to be a most worthy object of our endeavours in this direction. And for this purpose, clinical observation must go hand in hand with experimental physiology. The road to success is clearly and unmistakably pointed out to us; all we have to do is to follow it.

MR. N. W. HUBBARD, chairman of the Asylums Committee of the London County Council, opened a new asylum at Horton, near Epsom, on Saturday last. Accommodation is provided for 700 patients. Dr. F. Bryan has been appointed medical superintendent with Dr. Lewis as his assistant.

MALIGNANT DISEASE OF THE UTERUS:

ITS DIAGNOSIS AND TREATMENT. (a)

By FREDERICK HOLME WIGGIN, M.D.,

Surgeon to St. Elisabeth's Hospital; Gynæcologist to the New York City Hospital; President of the New York County Medical Association.

At the present time 7 per cent. of all deaths occurring in women over 45 years of age are caused by cancerous disease, and of these a very large proportion commence either in the neck or body of the uterus. Even at the present time the disease frequently runs its course during the patient's life. These facts and a few others will suffice to show that there is no subject of greater interest to the general practitioner and gynæcologist at the present than that of malignant disease of the uterus and its early diagnosis, for on this depends our patient's chance of permanent relief from her dreadful malady.

The results which have hitherto been achieved by

the gynæcic surgeon in the radical operations performed for the relief of sufferers from the disease which we are considering, while often followed by a low rate of mortality, have not been brilliant, when the recurrence of the disease is taken into considera-tion, for according to Thorne, hardly 30 per cent. of patients upon whom vaginal hysterectomy has been performed for malignant disease of the uterus, and who have survived the operation, remained well at the end of five years. This poor and discouraging result, he attributes (and the writer believes justly) to the fact that 70 per cent. of patients suffering from this disease, who present themselves to the surgeon for examination and treatment, do so in the later stages of the disorder, instead of in the earlier, as they should. The responsibility for this failure to recognise the disease during the earlier months of its invasion rests largely upon the general practitioner into whose hands these patients usually come first. and who seems to be largely imbued with the popular idea that all sorts of menstrual irregularities may occur during the last years of a woman's child-bearing period of life, without being of serious import, unless accompanied by a story of pain, foul vaginal discharge and evident cachexia, forgetting that, as Baldwin has recently pointed out, these last are the "symptoms, not of incipient, but of inoperable disease.

Williams, in a recent article on cancer, says that at the present time there are probably eight thousand women in England and Wales who are suffering from malignant uterine disease; while in the State of New York alone, during the year 1898, there were reported to the State Board of Health, 4,456 deaths as having occurred from cancerous diseases, a large proportion of which were undoubtedly those of the womb. These statements of the common occurrence of the disease, coupled by the fact which is borne out by the writer's experience both in hospital and private practice, that only a very small proportion of cases reach the surgeon at a time really favourable for operation, viz., before the disease has extended beyond the organ where it originated—must be his excuse for calling your attention to a brief review of what is already well known of this dreadful disorder, in the hope that further discussion of the subject may, by bringing out individual views and experiences, throw more light than we have hitherto had on malignant uterine disease in its earlier stages.

As is well known, cancer is a disease which originates in the epithelial structures. At the present time, though doubt still exists as to its etiology, the

recent work of Sanfelico, Roncali, Bra, Gussenbauer, and others, make it seem most probable that the time is at hand when the micro-organic origin of cancer, will be fully demonstrated and accepted as a fact. Among the chief indirect causes of the disease, may be enumerated heredity, locality, age, trauma, and infection caused by the following child bearing. A fair proportion of all who suffer from malignant uterine disease, as do those suffering from other forms of the malady, give a family history of cancer, showing that heredity plays a part by producing a predisposition to the disease. Location of residence is a factor of importance, as there are districts in which the disease is unusually prevalent, notably as stated by Park, in Bath, England, whose health officer recently reported that in his district there were 50 per cent. more cases than in neighbouring ones. Luckau, in Germany, where seventy-three deaths from cancer occurred in years, within an area comprised three City squares, four deaths one house. The same writer also twenty-three by two or occurring in one house. calls attention to the unusual prevalence of the disease in the districts immediately surrounding Buffalo, N. Y. Age is an important factor in the development of the disorder, for while it may occur at or during almost any period of life, it is most likely to make its appearance between the thirtieth and fiftieth year, but more commonly during the latter half of this period.

Women who have borne large numbers of children are more subject to it than are nullipara. This fact is clearly shown in a study made by Mullins, and published in the Australian Gazette for January, 1897, of 585 cases of females who had died in New South Wales of cancerous disease, 202 of whom had uterine cancer; of these 17 were sterile and two were single females, while the remaining 183 had been married and had given birth on an average to five children each. The other on an average to five children each. factors which enter prominently into the causation of the disease are cervical lacerations and neglected endometritis. The cervix is much more frequently attacked by the disease than is the body of the uterus, some observers placing the ratio as high as 50 to 1, but the writer believes that the uterine body is more often the seat of the disease than is supposed to be the case. Malignant disease, when located in the lower segment of the uterus, makes its appearance more frequently before the occurrence of the menopause than after it, and it is most likely to occur in those who have borne many children, and who, as previously stated, belong to the lower classes of society; while the disease in its corporeal form generally begins after the occurrence of the menopause, and in those women who have not conceived. The most common form of the disorder is adenocarcinoma, but occasionally it is of the sarcomatous variety, when it runs its course with great rapidity.

is suffering from a serious disorder.

But, as a rule, the disease manifests itself by the following constitutional symptoms. A general feeling of discomfort, loss of energy, anorexia, and an ill-defined sense of fulness and uneasy sensations referred to the lumbar, sacral and genital regions, accompanied with more or less marked increase of vaginal secretion or leucorrhea. If this discharge is examined, it will be found to be less viscid, and more watery than it usually is. If the patient is a woman between 30 and 45 years of age and has borne several children, a digital examination of the cervix will reveal the fact that it is enlarged and indurated and possibly slightly nodular. If we inspect it by means

Unfortunately the disease is frequently ushered in

with few or no symptoms to attract the attention of

the patient, or of her physician, to the fact that she

⁽a) Paper read before the New York County Medical Association, May 9th, 1899. Author's MS.

of a speculum we will find that on one or other side of a deeply lacerated cervix there is either a little hard nodule or an elevated area of mucous membrane, redder in colour than normal, and tending to bleed freely when touched. The disease at this early stage of its existence simulates very closely simple erosion of the cervix, but it is well to bear in mind that an eroded surface is smooth and velvety to the touch, has not infiltrated edges, and that on its surface the curette makes little impression. Any condition of this sort, however, that does not yield readily to ordinary treatment and tends to spread, should be regarded with more than suspicion, and the diseased tissue at once removed. It can then be examined microscopically and the exact nature of the disease can then be determined.

Some years since, the writer had a doubtful case under observation, one in which the disease was confined to the cervix, but not wishing to subject the patient to an unnecessary operation, a portion of the diseased tissue was removed and sent to a pathologist for diagnostic purposes. In about ten days an answer was received that the disease was malignant in its nature, and preparations were made to proceed with the removal of the uterus, when it was found that during the interval which had elapsed, the disease had made rapid progress. The case being no longer a favourable one for operation, the body of the uterus and the vaginal wall having become involved in the destructive process. Hence it has been the writer's custom of recent years to first remove all tissue of a doubtful character and have it examined afterwards.

The early stage of cervical cancer, it should be remembered is rather favourable to the occurrence of pregnancy, and also that when this condition coexists, the malignant disease makes rapid headway. At a later stage of cancer of the cervix, we will find on inspection either a series of warty growths which are friable and bleed easily, or that a deep ulcer with raised friable edges exists. At this stage, microscopical examinations of the diseased tissue is not needed to settle the diagnosis, and the patient begins to complain of hæmorrhage following coitus, of metrostaxis, menorrhagia, metrorrhagia, and escape from the vagina of foul smelling watery discharges, more or less tinged with blood, accompanied by pain. The sooner, under these conditions, the uterus is extirpated, the better will be the patient's chances, not only for immediate recovery from the operation. but for freedom from recurrence of the disease for at least three years, which as has been said, is the true test of the success of the operation,

When a patient who is between 45 and 50 years of age, or older, and who has never conceived, calls our attention to the fact that a few months after the cessation of her menstrual flow she has begun to fail in health, has also developed a profuse watery leu-corrheal discharge, and that her flow has recurred, a bi-manual examination of the uterus should be made, and will probably reveal the following conditions—viz., that the body of the uterus is enlarged and tender, and possibly nodular, that the external and internal os are both patulous. Such a patient should without delay be placed under the influence of an anæsthetic agent, and the cervical canal dilated and the uterine cavity explored. If the trouble is found not to be due to fibromata, the uterus should be removed, and the histological examination of the tissues made after this has been done, rather than before, as is usually the case. The curettage and delay incidental to this procedure before operation favouring the rapid progression of the disease, if it is of a malignant character.

It has been well said that the best treatment that a woman suffering from a carcinoma of the uterus can

recognition of her condition, when the removal of the diseased organ should follow, and a cure be

Attention has already been called to the fact that by far the largest proportion of cases that reach the surgeon do so after the disease has progressed too far to give a reasonable hope that the patient will be benefited by a radical operation. These patients can however, still have much done to relieve their distressing condition by placing them under the influence of an anæsthetic agent, and removing as much as possible of the diseased tissue. After this has been done the hemorrhage, which is often free, can be controlled by packing the cavity with pledgets of cotton wet in a solution of antipyrin, or, better still, with hydrozone, the pledgets being removed after a little while, and if the hæmorrhage continues the cavity should again be packed with similar pledgets, and it is rare that this procedure has to be followed more than three times. If the flow of blood continues after the third packing has been removed the cavity is once more to be packed, and the pledgets allowed to remain in place for twenty-four hours. The hæmorrhage having been controlled, the packing is removed, and the parts are thoroughly irrigated. The vagina and vulva should next be well anointed with a salve composed of one part of sodium bicarbonate and three parts of vaseline. The uterine cavity is then packed with small pieces of cotton wrung out in a solution of chloride of zinc, which should vary in strength from 50 to 100 per cent., according to the thickness of the remaining uterine tissue. Any excess of this solution must be rapidly removed with sponges, and the vagina should be filled with cotton soaked in a saturated solution of bicarbonate of sodium, Forty-eight hours later all this packing is to be removed, and the parts again irrigated. This treatment, which has been described by Penrose, has been followed for the past two or three years by the writer, both in hospital and private practice, with much benefit to his patients. The hæmorrhage is controlled, the offensive discharge disappears for a considerable time, and the patient being relieved in a large measure, of her sepsis, improves in appearance and gains rapidly in weight. Lucas-Championière advises the use in these cases of carbide of calcium, and gives the following technique for its application:—The vagina is first irrigated and then a small piece of the carbide is to be placed against the ulcerated surface. Bubbles soon appear showing that acetylene gas is being generated. The vagina is now to be carefully packed with iodoform gauze. This is to prevent the irritant effects of the products of decomposition of the carbide of calcium on the mucosa of the vagina and vulva. The packing should be allowed to remain in place for three or four days and then is to be removed. The parts should then be irrigated and all crusts removed. This procedure can be repeated at inter-vals of from two to six weeks as needs be. The claim made for it is that it stops hæmorrhage, thoroughly suppresses odour, and relieves pain in a large pro. portion of the cases so treated.

In conclusion, let me call your attention again to the fact that pain in these cases is an unreliable symptom, only occurring late in the disease except in certain cases, where the patient complains that she suffers from attacks of agonising cramp, like pains which recur during the latter part of each afternoon. Such a symptom when present in an elderly woman, is almost pathognomonic of cancer of the uterine body and is due to pent up secretions in that organ. Hæmorrhage is a constant symptom, but of the later stages of the disease, as is also the foul smelling vaginal discharge. Do not wait for a patient to tell you of this concatereceive at the hands of her physician is the early nation of symptoms before you think of a possi-

June 7, 1899.

bility of malignant uterine disease. The acceptance as an axiom of the statement that an increased flow of blood occurring before, at, or after the menopause is always due to an abnormality and needs careful investigation, as to its cause, would undoubtedly save innumerable lives. Let me call your attention to the fact that no form of malignant disease is so amenable to operative treatment, or promises more brilliant results than does that of malignant disease, provided only that the disorder is recognised, and the operation is performed while the morbid process is confined wholly to that organ, or, in other words, during the earlier stages of the disease, or before its advent, I would also have you bear in mind the fact that even when the disease is not recognised till it has passed the stage favourable for an effort to bring about a cure of the patient by extirpation of the diseased organ, that much can still be done in the way of palliative treatment, which will not only render the remainder of the patient's life more bearable to herself and her friends, but will actually

Our patients should be taught to return to us for examination within three months after confinement, and when uterine abnormalities are found they should be eradicated by operative means without delay. Patients should be further taught that the period of life between forty and fifty, which usually includes the menopause, is one of danger, and that during this period they should be more or less under the supervision of their physician, and on our part we should be more careful to examine locally all those who have reached this period of life, who complain of failing health, increased leucorrheal discharge, and the slightest menstrual irregularities tending to an increased loss of blood. In cases of doubt our patients should be given the benefit of it, by submitting them

anough be given the beneat or it, by submitting them at once to operation, while there is yet time and hope that the disease may be permanently removed.

And, finally, while we have good ground for believing that at a day near at hand, the micro-organic origin of cannot and its infectious nature will be fully established, and that once the life-history of the germ is known, we shall be able largely to prevent the occurrence of the disease, we must for the present base our hope of permanently benefiting a greater number of our patients suffering from this fearful trouble, not upon improved operative tech-nique, but upon an earlier recognition of the existence of the malady.

Clinical Records.

WESTMINSTER HOSPITAL.

Enemata Rashes.

Under the care of Dr. MURRELL.

WILLIAM G., æt. 14, was admitted with enteric fever on the eleventh day of illness. There was at first diarrhoa, but subsequently the bowels were confined. He had a motion on the twenty-first day, and on the evening of the twenty-fourth day he was given an enema of a pint of soap and water which acted freely. About thirty-six hours later a rash appeared on the abdomen, chest, arms as low as the elbows, and on the thighs. It was bright scarlet in colour, slightly raised, disappearing on pressure, and not attended with itching. It lasted forty-eight hours and was not followed by desquamation. There was no sore throat. On the thirty-eighth day the bowels were open twice, and then for four days there was no action. On the forty-second day the temperature, after having been normal for sixteen days, rose at 7.30 p.m. to 100.4 degs. At 8 p.m. an enema was given of a pint of soap and water. At midnight and at 8 a.m. on the following morning the temperature was 103.4 degs. At 9.0 a.m. a rash appeared similar in character to that

already described. It was confined to the chest, face, and arms, and there was no sore throat. The temperature fell at mid-day to 102 4 degs., and continued its downward course until it touched normal on the morning of the forty-sixth day. The rash gradually disappeared at the expiration of twenty-four hours, and there was no desquamation. The bowels acted freely from that time, and it was not necessary to give another injection.

Remarks by Dr. MURRELL.—As a case of enteric fever this patient presents no feature of interest. The point is that on two occasions after the administration of a soap and water enema there was a marked erythema precenting the ordinary characters of a scarlatinal rash. Such cases are not common, although they have been described. Dr. Suckling, of Birmingham, has recorded instances of a scarlet rash following the administration of enemata, and thinks that they are met with more commonly in children than in adults. Dr. Coupland, of Stoke-on-Trent, mentions a similar case in which the rash was followed by desquamation, and Mr. Staveley says that the rash is sometimes observed after the administration of a purgative by the mouth in cases of prolonged constipation. Some years ago Dr. Burford published a note on a mild form of septic toxemia after enemata. These cases are evidently examples of ptomaine poisoning. The rectum is capable of absorbing fluids rapidly, and when the hot soap and water liquefies the motion we get toxemia. Dr. David Walsh, who is an authority on such matters, points out that the rash is not unlike that which sometimes follows the injection of tuberculin, and suggest that it is an effort at excretion by the skin of an irritant substance. The elevation of temperature in our case is a feature of interest. The occurrence of enemata rashes, although apparently of trivial import, is worth recording, when one remembers the possibility of the rash being mistaken for scarlet fever and of the inconveniences which may attend a mistaken diagnosis.

In another case recently under my care the patient, a girl, æt. 13, suffering from that curious combination of symptoms so frequently described of late, tonsillitis, acute rheumatism, endocarditis and chorea, the enema was given at night and the rash was observed the first

thing in the morning.

ROYAL ACADEMY OF MEDICINE IN IRELAND. SECTION OF STATE MEDICINE.

The President, Dr. Tweedy, in the Chair.

MEETING HELD FRIDAY, APRIL 28TH, 1899.

ROOM DISINFECTION, WITH SPECIAL REFERENCE TO THE USE OF FORMIC ALDEHYDE.

By Drs. LITTLEDALE and KIRKPATRICK.

Dr. Littledale. - Experiments on the efficacy of formalin vapour were carried out in a room 28 cubic metres content, with no opening into it but the door, and 10 grains of formalin tabloids were vaporised in an "alformant" lamp. The yellow air coccus, coli commune, staphylolamp. The yellow air coccus, coil commune, staphylococcus pyogenes albus, bacillus typhosus, pus, sputum and putrid urine were the test objects exposed. Threads were steeped in emulsions of these various objects, wrapped in filter paper and lint, or concealed in the pocket of a coat or between the leaves of a book, or exposed quite open to the vapour. All the objects freely exposed were quite incapable of growing on nutrient media after a nine hours' exposure to the formalin, but concealment in a coat pocket or between the leaves of a concealment in a coat pocket or between the leaves of a book seemed quite sufficient to prevent their being acted upon to any degree, as all bacteria so exposed were not at all or only slightly hindered in their growth. The sputum was openly exposed on cover glasses, on which it had been let dry in the oven at 37 degs. C., and after exposure for nine hours no growth took place in broth for two days-that is, until the surface layer digested off and the deep surface was exposed, as could be seen by

the shaggy appearance of the layer on the cover glass- | Everything in the dried pus, which was openly exposed on gauze, was killed, except a leptothrix. Agar tubes of definite dimensions were inoculated over a sloped surface for a known distance and exposed just immediately after degs. C. Growths appeared in these tubes, but not over the whole length of the "smear," only the lower part furthest from the opening of the tube and terminating to a sharply-defined horizontal line, as appears to be the case whatever form of generator is used, as most investigators have had similar experiences. No inoculation experiments were undertaken on animals.

Dr. Kirkpatrick.—The apparent need for an efficient yet easily applicable mode of room disinfection is perhaps most marked in dealing with such a chronic infectious disease as tuberculosis. Such a method can practically only be obtained by means of gaseous disinfectants. Experience, however, has shown that the methods which until recently were employed for this purpose are very unsatisfactory. The author proceeded to examine critically those in most common use—i.e., sulphurous acid, chlorine, and bromine. The experiments of Koch were quoted to support his conclusion. As regards the first of these, that for practical purposes, it is useless. As regards the two latter, Drs. Fischer and Peoskaner have proved that to apply them efficiently is quite as difficult as to disinfect with germicidal solutions. The possibility of efficient room disinfection by means of formic aldebyde generated by Messrs. Zimmerman's "alformant" was then considered. Experiments by various authors were quoted to show what had already been done, and the apparatus was described in detail. It appeared that this process was very much simpler than any other of the modes of gaseous disinfection considered, while it was superior to any of them in point of efficiency. These conclusions would justify a very much more extended trial of this mode of disinfection than has hitherto been made, and lead us to expect that great practical good is likely to result to both patients and attendants from its use.

Dr. NINIAN FALKINER, reviewing the action of chemical disinfectants, said they acted in three ways—by oxida-tion, "direct or indirect," "reduction," or by "coagula-tion of albumen." Referring to the manner in which the disinfecting action of the formalin vapour stops at a clearly defined line in the culture tube, it suggests that the limit was caused by a chemical change in the vapour itself, produced by its action as a chemical oxidiser, it being reduced to the condition of an alcohol.

Dr. Knorr was inclined to believe that the stoppage of penetration at a certain line in the culture tube was due to eddying currents generated by the disinfectant, and that the explanation was physical rather than

chemical.

The President said that anyone working much among the poor knew the great objection they had to disinfection as carried out at present; a more effective and less disagreeable process was, therefore, much to be desired.

Dr. LITTLEDALE, replying, said the penetrating action of the vapour appeared to be inversely proportional to the vitality of the bacteria—a point which seemed to favour the suggestion made by Dr. Ninian Falkiner. Their experiments had not given formalin an exhaustive trial, as they had used a very weak gas.

Dr. KIRKPATRICK pointed out that among the advantages which formalin had over other gaseous disinfectants was the ease and rapidity with which it could

be used. The result did not depend so much on the length of time objects were exposed to the gas, but rather on its initial force. Six or seven hours would be sufficient to thoroughly disinfect with this vapour, and on opening the doors and windows after this the smell at once disappeared, which was not the case with sul-phurous acid or other gaseous disinfectants.

CANCER IN IRELAND. Dr. Martley read a paper on cancer in Ireland. After contrasting the deaths from cancer in Ireland and England—the former rate being roughly only 70 per cent. of the latter—he illustrated by maps its very unequal incidence in different localities, the parts most affected being the east of Ulster, Dublin, and Carlow. In conclusion, he moved a resolution that the Academy should appoint a committee to investigate the distribution of the disease in Ireland.

Dr. T. W. GRIMSHAW, C.B., Registrar-General, in seconding the resolution, remarked that the maps which were before them showed that cancer was prevalent in the most Anglicised parts of the country; for example they might look at Carlow, which they knew to be an old English colony, and Dublin, containing a large proportion of the population of English descent. Registra-tion was not as long in vogue in Ireland as in England, and consequently the returns were less trustworthy, as they had often to trust to memory for the ages of middle-aged people.

Dr. HAVILAND had noted the fact that cancer prevailed where there were sluggish rivers of considerable size and liable to overflow their banks, but they were ignorant as to the exact bearing this fact had on the occurrence of the disease.

Dr. John W. Moore, President R.C.P.I., explained the preponderance of cases in Dublin and Belfast by the fact that in country districts the doctors were often reluctant to give cancer as a cause of death, owing to the existing dread of the disease, on account of its hereditary nature; also the diagnosis of cancer was usually verified in the city hospitals by a necropsy, which was not the case in the country; in addition Dublin and Belfast received

cancer patients from all parts of the country.

The resolution was adopted by the meeting, and the

Section then adjourned.

WEST LONDON MEDICO-CHIRURGICAL SOCIETY

A CLINICAL meeting of the above Society was held in the Society's rooms at the West London Hospital on June 2nd, Dr. S. D. CLIPPINGDALE, President, in the

Mr. McAdam Eccles showed a boy with a large nevolipomatous tumour of the forearm, which had existed since birth.

The case was discussed by the President and Dr. Leonard Dobson, and Messrs. Rothery, E. P. Paton, C. B. Keetley, and Neville Wood.

Dr. LEONARD DOBSON and Mr. C. B. KEETLEY showed a young woman who had been successfully operated on for gastric ulcer three weeks previously. The patient for gastric ulcer three weeks previously. The patient bad suffered much pain for many months, and was in no way better in spite of prolonged medical treatment. Mr. Keetley opened the abdomen and found near the esophagus an ulcer, which had become adherent to the diaphragm. The adhesions were separated and the ulcer was scraped and closed. The patient made a good recovery.

The case was discussed by Messrs. Bidwell, Neville Wood, and Paton.

Mr. Bidwell showed a child on whom he had operated for tuberculous peritonitis, and a man on whom he had operated for extensive carcinoma of the rectum.

The cases were discussed by Dr. Dobson.

NORTH OF ENGLAND OBSTETRICAL AND GYNÆCOLOGICAL SOCIETY.

MEETING HELD AT LEEDS, MAY 19TH, 1899.

The President, Dr. Donald, in the Chair.

. SPECIMENS.

Dr. Hellier showed: 1. Fallopian tube with chronic salpingitis; 2. Uterus with acute puerperal inversion.
Dr. Braithwaits: 1. Parovarian cyst; 2. Cystic

Professor WRIGHT: A ring pessary retained for twenty-three years.

Dr. GEMMELL: Uterus removed for epithelioms of the cervix.

Dr. CROFT: 1. Series of specimens and microscopic sections of gynæcological interest; 2. Sarcoma of uterus following hydatid mole; 3. Fætal monstrosities. Dr. Hellier read the notes of a case of "Chronic Inversion of the Uterus," successfully reduced by Aveling's repositor. The labour was instrumental, but no hæmorrhage or signs of inversion were noted at the time. On the flith day the uterus was found at the vulva completely inverted. This was reduced by the medical man in attendance, but some months later as menstruation was excessive, an examination was made and the uterus again found completely inverted. Taxis under ether having failed, Aveling's repositor was applied. This effected complete reduction within 51 hours. It was, however, necessary to give the patient an anæsthetic to remove the cup of the repositor which had become incarcerated in the cervix.

Remarks were made by Dr. Young, Professor Wright, Dr. Lea, and the President.

Dr. Braithwaite read a paper on "A Method of Treating some Cases of Amenorrhea by Mechanical Irritation of the Uterus with an Intra-uterine Stem.' He advised that in certain cases of suppressed menstruation in which all other remedies fail to bring on the flow a vulcanite stem should be introduced. Suitable cases are those in which the patient is suffering from symptoms such as flushings, headaches, and signs of plethora. The treatment is of no value unless there are distinct menstrual molimina. It is of no use in cases of infantile The introduction of a stem is also contraindicated in the presence of flexions of the uterus, endometritis, or inflammation of the appendages. In some cases Dr. Braithwaite has succeeded in establishing typical menstruation: in other cases only a single flow of blood lasting a few days. The stems may be worn for some months, and Dr. Braithwaite has never seen any harm arise from their use. In many cases great benefit resulted.

Dr. Hellier considered that the risk of setting up endometritis and salpingitis in these cases was considerable.

The President held that stem pessaries should never be employed, and did not consider that amenorrhoes could be permanently cured by local means, although a hæmorrhage from the uterus might be mechanically caused. He believed that in cases in which they were tolerated they sometimes caused permanent amenorrhoes

Dr. Ra'Bagliati considered that amenorrhoes must be treated by attention to general nutrition, and held that mechanical irritation was not justifiable.

Remarks were also made by Drs. Young, Gemmell, and Wright.

Dr. Swalles read the notes of two cases of "Umbilical Hæmorrhage." Case 1 was a feebly nourished child, born of healthy parents. The cord came away on the fourth day, and the navel appeared normal. On the tenth day bleeding commenced, and continued in spite of local applications and ligatures. The child became jaundiced, and the urine was of high colour. The hæmorrhage proved fatal two days later. No poetmortem was obtained. Case 2, a well developed infant, born of healthy parents. Slight jaundice appeared on the fourth day. Two days later hæmorrhage came on. Various styptics were applied, and, finally, hare-lip pins were used. The bleeding, however, continued, and the child died on the fourteenth day. Poet-mortem the umbilical vein was patent up to the liver, but nothing else abnormal was found. There were no signs of infection.

Dr. Hellie said these cases formed a well-recognised group, and were often associated with hemorrhages from other organs. The cause was probably navel infection. The dry antiseptic treatment of the umbilical cord was strongly to be recommended.

THE Royal Institution celebrates its centenary next week, and, as the *Times* points out, that occasion ought not to be passed in silence. The Institution has, by unostentatious but thoroughly sound scientific work, contributed to the public benefit more lasting result than other more pushing institutions. It can point to the names of Count Rumford (its founder, in 1799), to Faruday, Davy, and Tyndall, besides many other less distinguished followers, and it may well be proud of such men.

THE GENERAL MEDICAL COUNCIL

EDUCATION AND REGISTRATION.

SUMMER SESSION, 1899.

Sir WILLIAM TURNER, President, in the Chair.

FIRST DAY-TUESDAY, MAY 30TH.

The sixty-seventh session of the Council was inaugu-gurated on Tuesday, May 30th, by the usual Introduc-tory Address, delivered by the President, who briefly reviewed the work before it. He announced, as stated last week under the head of Parliamentary News, that the President of the Local Government Board had "regretted his inability" to introduce a Bill for the reform of death registration for the present. He com-mented upon the heatile attitude taken by several of the mented up on the hostile attitude taken by several of the licensing authorities towards the clauses drafted by Mr. Muir Mackenzie bearing on the suspension of the right to use medical titles by persons whose names have been erased from the Medical Register for infamous conduct, adding that amended clauses had been drafted which, it was hoped, would disarm the opposition of the licensing bodies. He congratulated the Council upon the fact that a Bill had been introduced by the Lord Chancellor to prohibit the practice of medicine, surgery, and dentistry by companies. He referred to the complaint emanating from the College of Preceptors alleging "serious errors of statement and fact" Report of the Education Committee, and he intimated, in respect of the standard of general education, that in view of the number and importance of the replies received from various authorities on general education the period of reference would require to be extended.

In alluding to the penal cases to come before the Council the President called attention to a curious point connected with one of them, vis., whether a registered medical practioner, the salaried officer of a provident dispensary, could be regarded as "covering" an unqualified person who not only acted as dispenser, but visited and prescribed for the patients attending the dispensary, such dispenser being engaged, not by the practitioner in question but by the managers, The practioner, moreover, formally denies having consented to the dispenser visiting his patients. Passing on to the painful case of the late Mr. Hunter, he said he had directed a narrative thereof to be prepared for circulation among members of Council in view of a possible discussion. As might have been anticipated this résumé is marked "strictly confidential."

After the usual vote of thanks to the President for his address, various tables showing the results of examinations were received, whereupon Mr. George Brown called attention to the fact that in Part 1 of the final examination of the Victoria University there had been 33 rejections and 58 passes, and in Part 2 there were 41 rejections and 35 passes. He contrasted these results with those at the final examination for the same degree at the University of Edinburgh, where the rejections numbered only 18 and the passes 62, while for the M.B., B.Ch. there were 11 rejections and 137 passes. He wanted some explanation of this curious disparity in the results at the two universities suggesting that men would be sure to prefer universities where they would stand a better chance of getting through. He therefore moved that a special committee be appointed to examine and report thereon. In answer to a question by Dr. McVail he admitted that he was not personally acquainted with instances of men leaving the Victoria University to go to Edinburgh on this account, and he repudiated any intention of insinuating that there was anything wrong in the way in which the examinations at Edinburgh were conducted.

Dr. McVail was good enough to move that certain of the tables be referred back to the committee, but after an emphatic statement by the President as to the quality of the Edinburgh examinations the Council, on the initiative of Sir Dyce Duckworth, passed to "the previous questions." HONOUR TO WHOM HONOUR IS DUE.

Sir William Thomson pointed out that the table referring to commissions in the R.A.M.C. was a trifle ambiguous, and, as it stood, might be construed as meaning that the first thirteen places were won by the English Colleges.

The speaker's national susceptibilities were soothed by a promise that a footnote should be appended placing

the matter in its proper light.
Dr. GLOVER, alluding to the returns of the Society of Apothecaries showing that ninety-two persons passed in surgery and 169 in medicine, asked whether it was a fact that no candidate had passed the examination in both subjects.

Mr. Carter asked for notice of the question before answering and pointed out that of thirty-seven of their candidates for Army appointments thirty-five had been successful.

THE F.F.P.S.G.

Mr. VICTOR HORSLEY asked the Council to declare that the action of the President at the last session in ruling out of order his motion concerning the alleged insufficiency of the examination for the Fellowship of the Faculty of Physicians and Surgeons of Glasgow, was

contrary to the Medical Act, 1858.

The PRESIDENT pointed out that the original motion referred to a memorial addressed to the Council by certain fellows of the Faculty, but no such memorial had been received by him, though a letter from a Dr. Woods, addressed to no one in particular, had been received. A reply had been sent Dr. Woods to the effect that the Council did not inspect the examination for the fellowship, and there the matter rested. He urged, moreover, that the motion, as recapitulated by Mr. Horsley, was not the one which he had ruled out of order, and he called upon Mr. Horsley to make his motion conform to fact.

Mr. Horsley explained that he had understood the President to rule that the Council had nothing to do with the higher examinations of Corporations, and this, he felt sure, was an entire misapprehension. He explained the grounds in which he based his opinion, and urged that to allow the ruling to pass unchallenged would be to cut the Council off from a statutory right and duty which it owed to the profession and the public.

The President observed that his opinion, which he admitted was only that of a layman, was confirmed by the practice of the Council for the last thirty years. That practice was based on Section XXX. of the Medical Act, 1858. He did not think it was competent for the Council to go into the matter, the remedy being in the Glasgow Faculty itself.

Mr. George Brown asserted that under Section XXX the Council was entitled to examine into the sufficiency

of what were termed higher examinations.

Sir Christopher Nixon said that at first sight he thought the Council were entitled to sit as judges upon the higher examinations, but it would entail a herculean His own college, for instance, might refuse inspection of the examination for the membership, and the Council would be powerless. On the whole, he did not think the Medical Acts gave the Council power to deal with any examination other than that which entitled a man to be registered.

After some remarks by Mr. Teale and some further observations by Mr. Horsley, Dr. McVall pointed out that the motion invited the Council to censure the President for not having brought before the Council a memorial which had never reached him, and he moved "the previous question," which was carried.

INSPECTION OF DOCUMENTS.

The report of the Executive Committee codifying the standing orders regulating the inspection of documents belonging to the Council was received and adopted, and the Council adjourned to give the various committees a chance of getting their reports ready.

SECOND DAY-WEDNESDAY, MAY 31st. DIRECT REPRESENTATION.

After taking cognitance of certain resolutions passed

at the last meeting of the British Medical Association in favour of an increase in the number of direct representatives on the Council, Mr. George Brown moved that the Council express the opinion that the time has come to confer on the registered medical practitioners of England and Wales the power to return an addi-tional member. After shedding a tear over previous motions of like purport which "owing to the exigencies of business had not been dealt with," he explained why on this occasion he had restricted his demand to the English division. He pointed out that the number of practitioners in this division had increased from 16,978 in 1886 to 21,614 at present. With touching pathos he implored the Council to do the thing gracefully, and expressed the hope that those who had on former occasions voted against the proposal would see the propriety of yielding the point. The motion was seconded by Mr. VICTOR HORSLEY, and then Dr. GLOVER said a few words in support thereof. Admitting that the subject of increased representation had in the past been a somewhat ungracious one to the Council, he hoped that the passage of years had diminished, and in the future would still further diminish that hostile feeling. He claimed for the direct representatives a share in the good work done by the Council, and he quoted a remark by the late Sir George Humphry to the effect that the profession supplied the funds it was but fair that it should be fairly represented. He could hardly see hew the Council could refuse the modest concession suggested by Mr. Brown, and he emphasised the interest which was taken by the profession in the questions which had to be dealt with by the Council.

Sir William Gairdner disclaimed any desire to speak in opposition to the representation of medical practitioners but he dissented from the view that the representation was or ought to be a numerical one. That was evident from the fact that while the University of St. Andrew's, with it comparatively small number of graduates, was represented by one member, the College of Surgeons with its huge constituency had also to be content with one member. The point was that every institution connected with the medical profession should have a voice. He thought the status quo was fairly satisfactory, and he complained that the movers for additional representation "left out of account the great body of men who have borne the burden of the whole for so many years and had devoted so much time and attention to it." He said these movers were a disturbing element which they could very well do without. After a Parthian shot at the malcontents who, he said, would be found to be "men of no distinction" whatever he decided

to vote against the motion.

Dr. LITTLE failed to see that any valid argument had been adduced in favour of the change, and Sir RICHARD THORNE pointed out that only some 59 per cent. of practitioners had taken the trouble to vote at the last election, which did not look as if the profession as a whole cared very much about direct representation.

Mr B. CARTER intimated his opinion, in other words, that the resolution in favour of increased representation was "a put up job," and advanced the absurd argument that if the Council passed the resolution they would have to adjourn and await the decision of the Privy Council.

Sir William Thomson supported the proposal on the ground that the great mass of the profession was only represented by one-sixth of the Council. With regard to the term malcontents, applied by a previous speaker, to those who had moved in the matter, he pointed out that all reforms were the outcome of discontent, and he concluded by characterising the proposal as very moderate in view of the large interests involved.

Sir Christopher Nixon "could not see what advantage it would be to the profession to have a representative directly elected when they had a body such as the Council, composed of gentlemen willing to do anything they could to benefit the members of the profession."

(Ironical applause).

Dr. Pettigrew thought it would add to the labours of the Council, and Dr. LEECH thought it was undesirable to deal with the question piecemeal.

Dr McVail said he should, as heretofore, vote for the motion, but he deprecated an attitude which implied that

the Council had a vested interest against the general practitioner.

Mr. Brown having replied, the motion was summarily quelched.

REAPPOINTMENT OF REGISTRAR.

At this juncture Dr. McALISTIR proposed the reappointment of the Registrar, his being an annual appointment, and the proposal was carried nem. con.

Unqualified Dispensers.

Sundry communications were read from the Privy Council bearing on the appointment by medical men of unqualified dispensers, together with letters which had been addressed to that body on the subject. These having been assimilated, the President explained that the matter had been referred to the Council by the Executive Committee, which in the meantime had replied to the Privy Council to the effect that while accidents might occasionally happen from the employment of careless or incompetent dispensers such cases were probably very rare, and suggesting that probably the best protection was afforded by the responsibility of the practitioner for the acts or defaults of his servants.

Mr. Brown expressed dissatisfaction with things as they stood, and asked if the committee had any resolution to bring forward. Failing this he urged that they should appoint a committee or pass some resolution appoint a production of the committee or pass some resolution. urging practitioners who dispensed to employ only qualified dispensers. He asked on what data the committee had arrived at the opinion that such accidents

The President observed that no information had reached the Council to justify the supposition that they were otherwise than rare.

Mr. Carter pointed out that the matter had been referred by the Executive Committee to the Council for their decision, whereupon Mr. Brown formally proposed the appointment of a committee to consider the communications in question, and on being seconded by Dr. BRUCE, the motion was carried unanimously.

THE PREVENTION OF PERSONATION.

A report by the Executive Committee was read embodying the suggestion that no application for the restoration of a name to the Register under Section 14 of the Medical Act and Section 12 of the Dentists' Act should be entertained unless the statutory declaration contained a statement by a clergyman, magistrate, or registered practitioner establishing the identity of the

applicant.
Mr. Victor Horsley moved an amendment, which, after some discussion, was passed, to the effect that a special committee be appointed to report during the present session upon the best means to secure the identification of a person applying to be admitted to the Medical or Dental Register, and to prevent fraudulent registrations either on the first admission to the Register or subsequently. The whole subject of granting certificates of registration was also referred to the committee.

MIDWIVES' AND OPTICIANS' CERTIFICATES.

A report of the Executive Committee was read recommending a resolution to the effect that as midwifery legislation was before Parliament, it was not opportune to discuss the giving of certificates in midwifery. With regard to opticians' certificates the Council exercises no jurisdiction over opticians, but would be prepared to consider any properly substantiated charge of improper conduct made against a registered medical practitioner with reference to this subject

At the suggestion of Mr. Brown, the discussion was postponed.

RECIPEOCITY WITH FOREIGN COUNTRIES.

Communications from the Privy Council in regard to the right to practice of Italian practitioners in this country were read. They comprised one from the Italian Ambaesador asking whether Italian physicians could without a fresh diploma, exercise their profession in this country, or at least on foreigners resident in this country, and whether, if the answer were in the negative, Government would be willing to grant permission to Italian physicians to do so if the Italian Government

physicians residing in Italy. The report comprised the following resolution of the Executive Committee, "that they would welcome such a recognition of a right by English practitioners to practise in Italy as would enable Her Majesty in Council, under the provisions of Section 17 of the Medical Act, 1886, to extend similar privileges to Italian practitioners in this country. And that with regard to the other questions raised in the corre-And that spondence, the Executive Committee would refer the Privy Council to a letter of date February 24th, 1898, addressed to Sir Charles Lennox Peel, containing a reply by that Committee to certain questions received through the Privy Council from the German Ambassador as regards practice by foreigners in this country."

Dr. McVall urged that if this were conceded it would

be difficult to refuse similar concessions to other countries, and this he feared might work an injustice to

home made practitioners.

Mr. Victor Horsley concurred in the principle of reciprocity, but suggested that they ought to commence with the Colonies. In the interests of the profession he thought, however, that the Council should not accept the motion.

Dr. ATTHILL pointed out that it was far more in the interests of English physicians in Italy than of Italian practitioners in this country, and Sir RICHARD THORNE urged the cause of the "thousands" (?) of English physicians practising in Italy. After some further discussion tending to show that it was not such a farreaching measure as was alleged, the matter was referred to Mr. Muir Mackenzie to advise whether the privilege could be restricted to authorising foreign practitioners to practise only among their fellow-countrymen residing in this country.

THIRD DAY .- THURSDAY, JUNE 1st.

This was a penal day, and the first case to be called on was that of

MR. SAMUEL BINGHAM SHEKLETON,

of East Ham, who was charged with having aided and assisted one Rowland to procure himself to be registered under the name and with the qualifications of one Edward Joseph Nugent by making and producing fraudulent representations, and, secondly, for aiding and assisting Rowland to carry on practice as if he had been duly qualified.

Mr. Shekleton put in a very late appearance and narrowly escaped being condemned by default. Even when he did answer to his name he appeared to be in a very dazed condition and was unable to offer any adequate explanation of the charges alleged against him. He repeated incoherently that "he didn't know," that he had met Rowland in the street and had entered into conversation with him, learning among other things that his name was Nugent. He fixed the date of this occurrence at a time when the real Nugent was practising in the same street as the pseudo-Nugent, and he was flustered considerably when asked to explain how it was that the true and the false Nugent could have been practising for four years in the same street without the fraud being discovered. On the whole he cut a very sorry figure, and it did not take the Council long to decide to remove his name from the Register.

Some discussion took place as to the circumstances under which Nugent's name had recently been removed from the Register, and regret was expressed that it should have been removed under Section 14 instead of under the penal clause. It was explained that the name which had originally been removed under Clause 14 had been improperly restored on the strength of false representations, the restoration was thus invalid and the subsequent removal was merely reverting to the earlier state of things. On the motion of Dr. Church it was decided to call the attention of the proper authorities of New South Wales to the circumstances of the case re Nugent with a view to action out there.

The next case was that of

MR. JAMES JEROME MCKAY

Italian physicians to do so if the Italian Government registered as of Bally Roberts, Co. Cork, but practising were to engage to grant similar privileges to English in the Wandsworth Road, S.W. Mr. McKay owes his

little spell of notoriety to the fact that some months ago he was ordered by Mr. Braxton Hicks, the Coroner, to be prosecuted for perjury in connection with the evidence given by him at an inquest. In his evidence given before the Coroner the defendant stated formally that death was due to brain disease, and that he had carefully examined the heart, lungs, and other viscera, which were all healthy. He mentioned that the stomach contained milk, and that the bladder was partly full.

An examination made subsequently, on the Coroner's order, by the police surgeon (Dr. Kempster), assisted by other registered practitioners, proved that no real postmortem examination had been made. At the adjourned inquest Mr. McKay, after being cautioned by the Coroner, and after listening to the evidence of Dr. Kempster, swore afresh that his original evidence was correct. For some inexplicable reason the charge of perjury was dismissed by Mr. Plowden, the magistrate before whom it came, but the Coroner considered the case of sufficient importance to warrant his bringing it before the Council.

Mr. McKay was, therefore, charged not only with having failed to make the examination which was required of him, and with having failed to ascertain the cause of death, but also with having subsequently deposed before the Coroner contrary to the facts. The documents in support of the charge comprised the com-plaint of the Coroner, and a certified copy of the depositions at the inquest. The case was taken up by the Medical Defence Union, on behalf of the Coroner, and Dr. Bateman, representing the Union, called attention to the responsible nature of the duty of properly carrying out a post-mortem examination, any remissness wherein might work grievous harm to the lives and liberties of Her Majesty's subjects. The evidence of Dr. Kempster, the police surgeon, was to the effect that, having been asked to examine the body on which the defendant was supposed to have already made a post-mortem examination he found that the skull cap had only been partly sawn through, and that the edges could only be separated for about half an inch, so that a proper examination of the brain was impossible. On completing the section the brain was found to be quite healthy. There was an incision 41 inches long from the ribs downwards, but the peritoneum had not been opened and no examination had been made of the thorax, which was intact. On opening the thorax he found that one lung was the site of well-marked pneumonic consolidation, which indeed was the cause of death. The other organs were healthy.

After the case for the accusation had been concluded Mr. McKay was asked to come forward and make any statement he might wish concerning the facts that had been laid before the Council. He said he based his defence on the fact that he had been tried by Mr. Plowden and had been acquitted, and it was not right that a man should be twice punished (?) for the same offence. He urged that it was simply a difference of opinion between two medical men, but he did not question the accuracy of the description given by Dr. Kempster of the appearances of the body when asked to inspect it after he (the defendant) was supposed to have made his examination. He disclaimed any wish to say a harsh word against the Coroner, but complained that he had not been invited to be present at the second post-mortem examination. (This was ascertained to be the case.) He still adhered to his evidence, stating that he was convinced, from clinical observation, that death was due to the brain, so that a detailed inspection of the other organs was not really necessary. He said he could satisfy himself as to the condition of the brain without removing the skull cap, and as for the other viscera he had "felt" them. He said it was not true that the peritoneum had not been opened. Asked how he could describe the contents of the stomach without opening it, he said he felt something, and inferred that it was milk. He saw no reason to doubt that the bladder was as described though he had not opened it. He admitted that he had not opened the pericardium, or, indeed, the thorax, but he had felt the heart from the abdominal incision, and could assert that there was nothing wrong with it. In reply to the

President he said he had no defence to make and placed himself in the hands of the Council.

Nothing more remained to be done but to deliberate on the case in camera, and in a very brief space of time the Council found him guilty of the charge, and ordered the removal of his name from the Register.

The next case was one of a very different kind, it was indeed the peculiar case to which the President called attention in his introductory remarks. It was one in which

DR. WILLIAM STEWART,

of Denton, near Manchester. was charged at the instance of the Ashton-under-Lyne District Medical Society, in connection with the Denton and District Provident Dispensary, of which he is the medical officer, with having associated with an unqualified person named Burgess, who was alleged to be his assistant, in carrying on medical practice, and with being party to this person's administering medical aid and treatment as if he were a duly qualified medical man.

The case for the prosecution was brought forward by Mr. Hyde on behalf of the Medical Society, and Dr. Stewart appeared in person, accompanied by his legal adviser, Mr. Shawcross. Various statutory declarations were read setting forth that the assistant had visited and made up medicine for patients, and that he had given chloroform and assisted in operations. The report of the dispensary, which was put in, gave close upon 28,000 as the number of visits made during 1898, independently of consultations at the dispensary, operations, and confinements, and Mr. Hyde asked whether it was to be supposed that the defendant had done all this work himself, especially as the labours averaged 4'3 a week, and there the President Mr. Hyde abstained from going into the conduct of the dispensary in respect of the means adopted to obtain members. In answer to Mr. Brown, it was stated that the "trustees" of the dispensary were all labouring men.

Mr. Shawcross addressed the Council on behalf of the defendant, and produced statements in disproof of the allegations contained in the declarations put in by the prosecution. He denied that the visits, if any, made by Burgess were for medical purposes, or, if so, that they were made with the sanction or consent of the defendant. He pointed out that in so far as his relationship with the assistant might appear dubious, Dr. Stewart had expressed his readiness to be guided by the Council. He said he did not propose to tender Dr. Stewart as a witness, but, on reflection, he said that in order to avoid importing any prejudice by reason of his not doing so he was willing that Dr. Stewart should come forward.

Dr. Stewart then came forward, and, in reply to Mr. Shawcross, stated that he had been medical officer of the dispensary for ten years. Mr. Burgess was simply the dispenser, and was free to dispose of his time between 11 and 5 o'clock. He denied that Burgess had ever given chloroform for him, though he was present at the operations, and he had not even assisted him beyond washing the instruments afterwards. Burgess was there only from curiosity. In no case to his knowledge had Burgess ever visited patients. Burgess had been dispenser for about five years, and had gone through a medical curriculum at the Queen's University in Ireland, but he looked upon him not as a medical student but as a dispenser. He could not say whether Burgess had passed any examination. He said he himself could passet any examination. He said he himself could easily see from 80 to 90 patients daily at their homes, the district being of limited area. Questioned as to the numbers of visits to patients he said that it was an average, no record or book was kept either of the visits or consultations, or of the medicines dispensed. The whole of the work, except the dispensing, was done by himself. Questioned as to who gave the chloroform at one of the operations referred to by the prosecution (a case of strangulated umbilical hernia), he said he had given it himself while performing the operation, giving additional chloroform when necessary. He always did this, for he never called in any other medical man to assist him, though there were several in the neighbour-hood. He often gave chloroform without any other

person present. The other operation referred to was for cancer of the breast.

Cross-examined by Mr. Hyde as to how often he had to give chloroform in the 184 operations, he said in about one-half, and he had always given it himself. He could not say at how many of the operations Burgess had been present. Burgess merely attended at the branch dispensary for the purpose of making up his prescriptions. If he were absent at a confinement Burgess would not attend to the patients or give medicine. He attended all confinements himself.

Mr. Hyde pointed out that Dr. Stewart's salary increased according to the number of members, so that the medical officer was the primary gainer when members

were touted for.

Dr. Stewart, in reply to the questions, said that the dispenser was advertised for and appointed by the trustees. He said he had no knowledge of members being recruited by canvassers or touts. He himself lived six minutes' walk from the principal dispensary. He had signed no agreement with the trustees. When his attention was called to the fact that in the annual report of the dispensary Burgess was described as medical assistant, he said he had not previously noticed this detail, though part of the contents was furnished by himself. It was no pert of his duty to revise the report. He did not consider that he was doing wrong in giving chloroform and operating himself. The trustees paid the rent of the dispensary.

rent of the dispensary.

The case, having lasted long after the usual time for the Council to rise, the further consideration thereof

was adjourned.

FOURTH DAY .- FRIDAY, JUNE 2ND.

THE CASE OF DR. STEWART.

The first item on the programme was the adjourned consideration of the case of Dr. Stewart, of Denton, near Manchester, the evidence wherein is contained in yesterday's report. The Council retired into their lair to deliberate, and judging from the length of time they remained sequestered from the public gaze, the problem must have given rise to a good deal of discussion.

must have given rise to a good deal of discussion.

Dr. Stewart was recalled and was asked a number of questions. He adhered to the statement that the dispensary was managed by a committee who nominated the dispenser without consulting him. The only subscribers to the "Provident Dispensary" were the paying

members.

Ultimately the Council arrived at the conclusion that Dr. Stewart was guilty of the charge brought against him, but in view of the fact that the circumstances were novel and somewhat peculiar, it was decided to defer sentence until the November session, when Dr. Stewart will have to put in an appearance again and submit to a further interrogatory.

THE CASE OF MR. NEVILLE HOLLAND.

Mr. Neville Holland, practising in Lambeth, registered as L.S.A., was charged with covering one Blumenthal, in connection with a dispensary in Tyers Street. He was also charged with being a party to attracting practice to the said surgery by public advertisements. It was also alleged against him that he had violated the undertaking given by him to the Council in November, 1895, that if his name were restored to the Register he intended to act as an assistant to a registered practitioner.

The complaint was laid by the coroner for South-west London, and was brought before the Council by the

Medical Defence Union.

The evidence presented nothing of special interest. It was an ordinary case of "covering" under aggravating circumstances, because the most unblushing advertisements were shown to have been circulated among the public with the object of attracting periods.

public with the object of attracting patients.

In defiance of the evidence the defendant had the audacity to assert that Blumenthal never attended patients, at any rate to his knowledge. As to the advertising he pleaded ignorance of the fact that this was forbidden, and he urged that in starting a dispensary it was customary to anounce the fact in this way.

After the usual deliberation is camera the Council found him guilty and ordered his name to be removed from the Register.

THE CASE OF WILLIAM HENEY COSSENS, of Derby Street, Prescot, was a peculiar one, but it will suffice to state that it having been proved to the satisfaction of the Council that Cossens had been convicted of a misdemeanor and sentenced to four months imprisonment, his name was ordered to be erased from the Register.

This completed the business for the day.

The Council on Saturday was occupied almost exclusively with dental business.

France.

FROM OUR OWN CORRESPONDENT.]

NATURE AND TREATMENT OF HERPES ZOSTER.

Paris, June 4th, 1899.

Prof. Abadic considers that the nature of the eruption of herpes zoster had been until lately misunderstood. For a long time it was taught that this affection was a trophic trouble of the skin, due to a malady of cutaneous nervine branches commonly called neuritis. However, M. Brissaud endeavoured to destroy that theory by showing that the region where the vesicles were found did not always correspond to the topographical distribution of these nerves. On the other hand, he attributed the herpes to atrophic trouble of medullary origin. M. Abadic refuses to associate himself with either of those opinions; for him the lesion is exclusively provoked by a pathological condition of the terminal arteries and the

vaso-motor nerves presiding over their dilatation in the

region where the eruption is seated.

In ophthalmic herpes, for instance, the eruption which characterises it, is developed exclusively on the territory supplied by the first branch of the third pair, by the ophthalmic branch of Willis. The vesicles run a vertical course on the forehead near the median line, and in appearance along the tract of the frontal and the supraorbital branches. Sometimes also the eruption is seen on the nose and on the eye of the same side. It is thus that it is frequent to observe these vesicles on the cornea, where they produce ulcerations difficult to cure. If the ophthalmic herpes was due, as it had been believed up to the present, to a simple inflammation of the third pair of nerves, how could it be admitted that the common trunk being inflamed, only one of its branches should be affected? With the theory that I maintain, continues M. Abadie, the eruption developes itself in the vascular region supplied by the supra-orbital, frontal and nasal arteries and which is really the fact. In the interior of the cranium, on the very trunk of the third pair of nerves are attached numerous nerve filaments of the great sympathetic coming from the carotid plexus, which itself takes its origin from the superior cervical ganglion. All these filaments are spread out in the walls of the arteries off shoots of the ophthalmic artery and in their terminal branches. If, then, we suppose that an inflammatory process attacks the trunk of the third pair or the ganglion of Gasser, it follows that it will influence at the same time the filaments of the sympathetic above mentioned which accompany the third pair, yet preserving their own individuality. The lesion of the sensitive elements of the third pair will

determine sensitive troubles, hyperæsthesia, anæsthesia in the regions supplied by them, while that of the vasomotor filamenas will produce a continued and excessive dilatation of the terminal arteries that they embrace, dilatation sufficient to provoke a rupture even of the succeeding capillaries. It is thus that the seat of the eruption is not exactly that of the nerve filaments, but of the arteries which they accompany. If, in the great majority of cases of ophthalmic zona, no vesicles are seen in the regions of the superior or inferior maxillary, the reason is that the vaso-motor nerves of this territory have not the same origin as those accompanying the ophthalmic artery, they come from another source.

M. Abadie believes that the best remedy for zona and for the ophthalmic form in particular, is quinine in large doses, and that fact constituted an additional proof of the theory he advances, as quinine is a vaso-constrictor agent, acting on the sympathetic and producing contraction of the arterial vessels.

THE FRENCH CONGRESS OF MEDICINE.

This Congress is to open at Lille, Professor Grassier of Montpelier, being President. The promised communications deal with a variety of interesting subjects, and the list of speakers include some of the best-known physicians and surgeons in France.

Germany.

[FROM OUR OWN CORRESPONDENT.]

BERLIN, June 2nd, 1899.

At the Surgical Congress Hr. Kronlein, Zurich, read a paper on

CYSTIC KIDNEY.

He said that surgeons had not taken much practical interest in the subject as the disease was generally bilateral and inoperable; they had therefore to limit themselves to those rare cases in which it was unilateral. Some surgeons said there were no such cases. There were such, however, probably acquired, and not of a congenital nature. He showed a preparation. The patient, a woman, æt. 38, came to him in August of last year, with a tumour in the abdomen. The diagnosis was tumour of the left kidney half filling the abdomen, reaching from the pelvis to the diaphragm, and extending beyond the middle line. The patient was three months pregnant. No exploratory puncture was made. At the operation a transverse incision was made from the left attachment to the umbilicus. There was no great difficulty, although large vessels ran over the capsule. The right kidney and liver were healthy. The tumour was a large cystic kidney. (Adenoma cysticum.)

Hr. Jordan, Heidelberg, read a paper on The Origin of Perisenal Suppuration from Metastatic Abscesses.

He said that in renal abscesses, besides the ordinary suppuration, both pneumococci and bacteria coli were found. Three cases of his own had originated in pyæmic metastases. The first was a man of 30 with a carbuncle in the inguinal region. After a week high fever came on with violent pain in the left hypochondrium, where a tumour was found which was diagnosed as renal. Then a tumour formed in the right side, the fever went higher, vomiting came on, and a pulse of 130. Both tumours had an elongated form. The right kidney was opened up, the capsule was intact, but the kidney was enlarged to about

double the normal size. An abscess was opened on the posterior aspect, about the size of a walnut. The wound was packed and treated openly. The temperature fell at once. The left-sided tumour disappeared on the fifth day of the operation. The urine was normal throughout.

On June 20th, 1898, a woman came under treatment with panaricium of the right index finger. An incision was made. Fourteen days after she had pain in the right hypochondrium. By the end of July an elongated tender tumour was felt which appeared to be connected with the kidney. The urine was normal. On the kidney being exposed, the fatty capsule was found to be inflamed. An abscess the size of an apple was found in the kidney parenchyma. This was incised and packed, and treated openly. Complete recovery. Staphylococcus aureus was found in the pus.

The third case was that of a man who had suppuration from a cut finger. Pain came on in the left hypochondrium, and an abscess was diagnosed.

Besides the multiple pyæmic abscesses, solitary ones were met with in the kidney. When large they presented characteristic symptoms. By extension to the capsule they led to para-nephritic suppurations. This might be prevented by early operation.

Hr. Zondek, Berlin, showed some beautiful maceration preparations, illustrating the arterial system of the kidney and its importance in renal surgery.

Hr. Krause, Altona, read a paper on

THE OPERATIVE TREATMENT OF SEVERE OCCIPITAL NEURALGIA.

He said that very severe attacks were not limited to one branch of a nerve, but extended into others. Insevere occipital neuralgia, all the branches of the occipital nerve were affected, and thus half of the back of head, the ear, jaw, and the upper part of the neck of the side affected. It could not be determined that one of the nerves was the cause of the affection. Each of the nerve trunks of the occipital could be so small that another acted for it, and on the other hand one usually small and unimportant might by its size become chief of interest. In order to get a good result from operation, therefore, one ought not to satisfy oneself by operating on one stem; he, therefore, advised the resection of the whole of the nerves. He began the skin incision 3 ctm. beneath the occipital protuberance, carried it outwards to the angle of the jaw, then along the jaw to the attachment of the lingual bone. The smaller nerve fibres were difficult to find, and were to be prepared from the periphery to the centre. The ganglion was reached without any operation on bone, as it lay outside the vertebral canal. By this the first and second stems were distinguished from the other vertebral nerves, the third passed into the vertebral canal and had its ganglion there.

Hr. Garré, Rostock, said that in simple resection of the trigeminus recurrences frequently took place, through regeneration of the nerve, and even when the whole nerve was twisted out recurrence sometimes took place, and even when the Gasserian ganglion was removed (contrary to opinion expressed by Krause and Horsley) recurrence had taken place through regeneration of the nerve. In case of trigeminus neuralgia in an old gentleman of 68, the third nerve was resected in 1890, and in 1872 recurrence having taken place a second resection was performed by Madelung. Recurrence again took place. In May, 1895, the Gasserian ganglion

was removed. A year and a half later recurrence again took place. Then operation was again performed; no trace of the Gasserian ganglion was found, but a small branch running through the foramen ovale. This was removed. Recurrence, March, 1898. Although regeneration of the nerve appeared out of the question, the first was sought for and resected. The neuralgia, however, continued, and in November the third was looked for, when a strong, vigorous stem was found and removed for the third time. Under the microscope the nerve showed normal nerve fibres. Then recurrence took place in the second branch. This was cut down upon and again resected. The patient was now free from pain, but one could not say with certainty that it would not recur again.

Hr. Krause said that regeneration of the trigeminus had never been known after removal of the Gasserian ganglion. He had removed it eighteen times, and had never seen recurrence take place.

Austria.

[FROM OUR OWN CORRESPONDENT.]

VIRNNA, June 2nd, 1899.

STENOSIS PYLORI. AT the "Geselsschaft der Aerzte" Weinlechner presented a female patient to the Society on whom he had operated several times. In 1894 she came to him with stenosis of the pylorus and dilatation of the stomach, for which he performed pyloric resection with excellent results The microscopic examination of the resected portion gave no confirmation of malignancy, neither was any trace of cicatrices or ulceration to be discovered. The following year she was readmitted to hospital with perityphlitis in the region of the vermiform appendix. Another operation was performed and the appendix removed. At this time the stomach and pylorus were normal. In 1896 the stomach trouble returned, for which laparotomy was again undertaken, when a few adhesions between the stomach and omentum, with parietals of the abdomen were observed. A portion of the bowel was again resected along with a few glands of the mesentery that had become calcareous.

After this recovery the patient remained free from any trouble for some seven months, when the stomach troubles recommenced, with vomiting and a square gurgling area about 4 inches in extent immediately below the umbilicus, which persisted in spite of sedation and irrigation of the stomach.

At last gastro-enterostomy was performed, with favourable results. The patient has increased in weight since the operation to the extent of 91 kilogrammes, while the dilatation of the stomach has diminished, so that it took 13 inches less sound to reach the lowest part now than before the operation. Weinlechner gave it as his opinion that the stenosis in this case was due purely to hypertrophy of the mucous membrane. Zinsmeister recorded a somewhat similar experience in a case recently under his care. The patient was suffering from cicatricial pyloric stenosis; he performed jejunostomy without relief. finally performed gastro-entero-anastomosis with complete success.

RUPTURE OF GALL-BLADDER.

Hochenegg's views expressed at the last meeting. The first was a case that came to him with the diagnosis of lead colic. Laparotomy was performed, and the contracted gall-bladder was found with an opening leading into it and gallstone blocking in the orifice. In spite of the total extirpation of the gall-bladder, cleaning and draining of the peritoneum, the patient died from general peritonitis.

The second case was that of a female whose illness was early diagnosed as one of rupture of the gallbladder. Laparotomy was at once performed, the cavity well washed and drained with the best results.

This accident is by no means a rare one in the history of the Vienna "Krankenhaus," the average being two each year. The correct diagnosis of such cases can only be obtained by the history of the case with colic, &c., and the symptoms of perforative peritonitis.

Hochenegg differed from Ullmann in the diagnosis, for he was convinced they could easily be diagnosed. He added that his cases differed from Ullmann's in that the bladder discharged into the cavity of the peritoneum. Again he differed from Ullmann as to the rarity of those cases. In infants he thought the case was very rare, there being only one case on record by Braun where the gall-bladder was found ruptured, after birth, with the contents in the peritoneum.

Ullmann rejoined that all his cases had discharged into the peritoneum.

Gussenbauer added that Hochenegg's did not all rupture into the peritoneum since, as he had admitted, there were extensive adhesions around the stomach he had to remove.

Paltauf thought a distinction must be drawn in the description of these cases according as the rupture is due to necrosis, due to high tension of the viscus, or simply to a rupture of the wall of the organ without any ulceration. The former is more likely to become sealed round the seat of the rupture and to prevent discharge of the contents into the peritoneal cavity. Where the rupture is sudden the contents will, of course, prompt'y find their way into this cavity.

Special Articles.

THE INTERNATIONAL CONGRESS ON TUBERCULOSIS.

THERE could not well be a more worthy subject for discussion at an International Medical Congress than the prevention of tuberculosis, a disease which wreaks its ravages among all classes of society without regard to age, sex, or nationality. The interest which the subject has excited of late throughout the civilised world is significant of a tardy awakening from the lethargy into which the public had fallen, crushed by the very magnitude of the evil with which we are now called upon to cope. The English Government was represented by fifteen delegates of acknowledged eminence, and the names of the foreign participants is a sufficient evidence of their special competence.

In Professor Virchow's admirable address the situation is defined with masterly lucidity. recognises the existence of purely local tuberculous lesions which do not necessarily imply contamination of the carcass as a whole, the necessity for closer Ullmann brought forward other cases in support of inspection of the meat supply is insisted upon, care being

taken to secure that foreign imported meat shall not escape control, an excellent principle, though its application will be found to present serious and possibly insurmountable difficulties. Owing to the prevalence of tuberculous disease among milch cows the destruction of all infected animals is declared to be impossible, but unless this can be done the value of the tuberculin test as a means of detecting latent tuberculosis in animals is greatly impaired. If animals which give the characteristic reaction are not to be destroyed, what is to be done with them? Failing this wholesale destruction we are fain to fall back upon methodical sterilisation of milk. but this, in view of the habits of the poor, can never afford more than partial and incomplete protection. The Professor dwelt upon the importance and frequency of tuberculosis among swine, a point which has not hitherto received much attention in this country, possibly because it is less common here than in Germany, though we are hardly in a position to affirm that such is the case. In swine, we are told, the seat of infection is especially the glands in the neck. As the form of tuberculous disease which affects poultry is not identical with that from which human beings suffer the danger of infection from this source is assumed to be non-existent.

It is comforting to have from Professor Frankel a confirmation of the view that the bacillus of tuberculosis only flourishes in the living tissues, and that it promptly loses its virulence when exposed to light and desiccation. It follows, speaking generally, that the risk of infection is confined to a zone around each focus of the disease. Unfortunately, the dense aggregations of underfed and unhealthy persons which are found in all large cities provide a peculiarly favourable soil for the propagation of the disease on these lines.

Professor Pfeiffer laid stress on the important role played by secondary infections, indeed, it would seem that it is not until these appear on the scene that the condition of the tuberculous patient becomes more or less hopeless.

Professor Löffler dismissed the onetime doctrine of heredity as unproved and scientifically improbable, but, though we agree that tuberculosis is, at any rate in the vast majority of instances, due to infection from without, we see nothing inherently impossible in the transmission of the disease as such. Syphilis is also a disease due to infection from without, yet it is certainly capable of parental transmission as we know but too well.

Professor Kirchner touched on the delicate subject of the marriage of tuberculous subjects, but, however desirable it may be in the abstract to prevent such marriages, we fear that the matter is one which must be left to the good sense of better educated communities. Still, as it is a matter in which medical men are sometimes called upon to advise, it is well that one's mind should be fully made up, if indeed it were not so before. More to the point were his remarks on the imperious necessity of having recourse in all cases of tuberculosis to the precautions which experience has shown to be necessary in respect of persons suffering from a communicable disease. Patients for the most part are perfectly willing to do what lies with them to prevent their becoming centres of infection, and when otherwise they probably sin more from ignorance than from any indisposition thereto.

sanatoria for consumptives, a departure which is largely due to British initiative. The more we consider the figures the more obvious does it become that the task is one which will heavily task the resources of the richest states, unless ably seconded by private munificence and local effort. It will be necessary to secure the co-operation of friendly societies, sickness insurance associations, and public bodies generally if the movement is not to fall through. So general is the interest in the subject and so nearly does the problem touch all classes of society that we are sanguine of ultimate success. At the same time, as the Professor pointed out, sanatoria can only deal with the fait accompli, though by facilitating recovery we diminish pro tanto the tendency of the disease to spread beyond its actual foci.

The problem with which we have to grapple is hydraheaded, but science has enabled us to recognise these heads, and our attention must be devoted to their extinction by an attack all along the line. The problem comprises the better housing and the better alimentation of our labouring classes, their education in the means of combatting the foe, the partial segregation or violation of the sick, and the protection of the healthy. Science has already done much, but more, much more, remains to be done. Let us hope that the wave of public opinion which has traversed the old world, will not subside without leaving a permanent mark on the preventive medicine of this century.

The Operating Theatres.

ST. THOMAS'S HOSPITAL.

Myeloid of Upper and Lower Jaws treated by ENUCLEATION.-Mr. W. ANDERSON operated on a girl, æt. 24, for myeloid tumours of upper and lower jaws. The patient had noticed during the last four years an enlargement of the right side of the body of the lower jaw; this increased slowly and painlessly, and two years ago a small swelling appeared at the root of the nasal process of the superior maxilla; there was no glandular enlargement. On admission the right half of the body of the lower jaw was found to be increased to the size of an ordinary lemon by a growth within the bone; most of the teeth over the growth were lost, but the gums were entire; the swelling was uniform in surface and invested by a shell of bone. A similar but much smaller growth was found in the superior maxilla at the root of the nasal process. The patient was an uræmic undergrown girl, suffering from chronic menstrual disturbances. Mr. Anderson made an incision a little below the body of the lower jaw, dissected down to the surface of the tumour. chiselled away the whole of the shell of bone forming the anterior wall and exposed a soft endosteal growth; this was carefully enucleated with a scoop, the interior of the shell was wiped out with cyanide gauze, and the wound closed by subcuticular suture. The tumour of the upper jaw was treated in a similar way. Mr. Anderson remarked that the co-existence of two myeloid growths in the same patient was very rare; there could be no doubt of its nature, and it was this certainty that led to the treatment of the condition by enucleation rather than by complete excision. It is well known, he said, that the myeloid growths have little Professor von Leyden brought forward the question of | tendency to multiply by the infection conveyed through

the blood or lymph streams, or to spread by infiltration of the adjacent tissues; hence if the cell growth can be completely removed the prospects of a permanent cure are very good. The complete excision of the tumours would have given rise to great deformity, while the plan adopted would leave only a linear scar.

Histological examination made a few days later confirmed the diagnosis.

HOSPITAL FOR SICK CHILDREN.

OPERATION FOR OLD-STANDING EMPYEMA. - Mr. ABBUTHNOT LANE operated on a child æt. about 6 years, who presented a small obliquely placed sinus in the front of the right chest from which a quantity of pus exuded. On passing a probe into this sinus the instrument entered the general pleural cavity. Mr. Lane exposed three ribs in the lower and back part of the chest, and removed three inches of their length with the intervening intercostal muscles, &c. The pleural cavity was found to be open throughout the whole of its length except where the diaphragm had formed adhesions to the lower limit of the chest. It was not possible to recognise the lung on the inner wall since it appeared to have collapsed completely, but this was not surprising, as this condition of empyæma had existed for about six months. The pleural cavity was cleaned as thoroughly as possible, and then closely packed with iodoform gauze. This process was repeated on two subsequent occasions under an anæsthetic. On the last occasion the contents of two large bottlefuls of decalcified bone were inserted into the cavity, these just sufficed to fill it up to the level of the ribs. A quantity of iodoform was dusted over the wound and iodoform gauze applied over it. These dressings were not changed for three weeks. Mr. Lane said that the decalcified bone used was that suggested by Dr. T. W. Robinson, Honorary Surgeon to the Huddersfield Infirmary, and described by him in the Lancet of October 2nd, 1897; Dr. Robinson employed it with the idea that it would form a temporary scaffolding for the granulation tissue cells, which would by this means be kept alive and not discharged from the surface as pus. He obtained most excellent Mr. Lane had employed the results by its use. method for a long time with complete success; he had never before used it in such large quantities as in this particular case, although he had on one occasion filled the space which had been originally occupied by half the length of the shaft of the femur in an adult with it. He pointed out that it is exceedingly important that the decalcified cancellous tissue should be kept at rest after the insertion of the decalcified bone, and he hoped that the mobility of the chest wall and diaphragm was sufficiently limited for this purpose.

DR. J. B. BRADBURY, Downing Professor of Medicine in the University of Cambridge, has been appointed Croonian Lecturer for 1899 at the Royal College of Physicians of London. "Sleeplessness and Hypnotics" has been chosen as the subject of his lectures which will be delivered at the College on June 20th and following days.

DR. PYE-SMITH, Physician to Guy's Ho-pital and a member of the Senate of the University of London, has been appointed to the seat on the General Medical Council, vacant by the death of Sir Wm. Roberts, as representative of the University.

"SALUS POPULI SUPREMA LEX."

WEDNESDAY, JUNE 7, 1899

DISPENSING BY DOCTORS.

A CONTEMPORARY professing to represent the English general practitioner speaks of "the claim which has been advanced by chemists to a monopoly of dispensing" as "unwarrantable" and impossible, a statement which shows how far the spirit of trades unionism will carry those who have their eye fixed on their own pecuniary interests. We admit that the complete divorce of the medicine trade from medical practice in England has come to be almost impossible, as has also the purgation of the chemist's trade from counter prescribing, but we unfeignedly regret the fact and maintain that the desire that the doctors shall stick to their own legitimate business of diagnosing and prescribing is, in no respect, more "unwarrantable" than the contrary demand, which our contemporary is never weary of proclaiming, that chemists shall stick to their's and abstain from exercising the doctorial functions. In this matter we suggest that the just rights of doctor and chemist are on all fours. The chemist may abuse his position by advising and prescribing upon a dangerously insufficient knowledge of medicine and surgery, and by doing so without seeing the patient, but, on the other hand, we cannot claim for our profession any expert acquaintance with chemistry and pharmacy nor any facilities for making up medicines equivalent to those enjoyed by the chemist. The trades union bias of our contemporary is manifested by the text which it selects for its sermon, i.e., the employment by medical practitioners of unqualified boys to make up the principals' medicines, the result of which practice in one recent case was the fatal poisoning of a patient, and it holds that it is quite legitimate for a general practitioner to employ such an assistant on his own responsibility, and it protests in anticipation against any public opinion to the contrary. But our contemporary forgets that, for years past, it has exhausted its energy and its logic in a screech against the analogous practice of employing unqualified assistants by general practitioners. It has represented that the assistant employed for diagnosis and visiting and prescribing should be put to the sword without mercy, unless he can produce a medical qualification, and yet it now represents that the analogous assistant may with perfect propriety be employed for measuring out medicines and interpreting prescriptions without producing a pharmaceutic qualification. An observer must be wilfully blind who fails to discern that the difference between the two cases, from our contemporary's point of view, is that the unqualified medical assistant was a serious competitor with the general practitioner and diverted many of the fees which the practitioner might receive, into the till of his employer the doctor, while the unqualified dispenser is the essential jackal of the general practitioner and enables him to earn large profits on medicine vending which he could not obtain without his help. The whole dispute is a question of shop and of money, and does not deserve to be raised to any higher level.

Apart, however, from these sordid interests there is an obvious reason why the function of the general practitioner in country districts cannot be, at least at present, divorced from dispensing. Suppose the practitioner derived no profit, direct or indirect, from the medicines which he supplies, he would, nevertheless, be compelled to continue the supply because there exists in most agricultural districts, no other means by which his patient could be supplied. Qualified chemists do not grow on the roadside, and it would be simply impossible for a practitioner to send his patient's messenger to the neighbouring town for all the medicines which he found it necessary to prescribe. He has no choice but to keep them in his own house and send them to the patient when made up, and he must, so far, usurp the function of the chemist, but we can see no just reason why, if he employs a dispensing assistant, he should be allowed to employ one without knowledge. In town practice we can discern no element save the money profit which should induce the practitioner to make up his own medicines, but, if he sees it to be his interest to do so, we do not discern how he can justly complain if his neighbour the chemist follows his example.

THE QUESTION OF "EXERCISE."

It is well for us to have clear ideas on what kinds of exercise and games we ought to encourage, and what we ought to object to. The spirit of competition is now entering so much into nearly all the games, which were formerly encouraged for the exercise they afforded, that instead of doing good, they may do harm. In such exercises as rowing, skating, swimming, and dancing, the chief pleasure enjoyed is

not from competing with and defeating others; but from the curious effect of movement upon the nervous system, whether the individual is alone or in harmony with others. We see this in many animals, indeed, more than in our own species. What we have to consider now is whether instead of this being the object of the games of to-day, the desire to excel and attract attention does not prevail more than it ought, whereby the good effects of exercise upon the system are changed into the bad results of excess. It is well for us to consider carefully what are, or ought to be, the objects of exercise, and whether it is the mental, the moral, or the physical development that we seek for, when exercise is encouraged. We doubt much the value of "gymnastics" when we desire to improve the two first, the most important parts of education, and if any exercise has no object but that of developing the muscles, without considering its influence as a recreation, it is right that we should discourage it when we find it being forced upon those who are being educated for the work of life. When we have to consider the various games and recreations which enter into the school and college life of the rising generation, we are justified in preferring those that afford some occupation for the mental as well as the physical qualities of the individual. It is for this reason that we doubt the value of the gymnasium in comparison with such exercises as are afforded by cricket, rowing, tennis, golf and other kinds of recreation, which take the mind away from the subjects which have occupied it and give it rest by change of occupation. It is well for us to have some distinct principle to guide us in this matter, for there is no subject of greater importance to a nation than the education of its youth. It seems to-day as if the desire of exhibiting to spectators is influencing our games most prejudicially. The true enjoyment and benefit of games is greatly marred when vanity is excited by the attention of on-lookers. There is too much professionalism, and too much of the spirit of business in popular recreations at present to make them serve their best purposes, and justify us in encouraging them. And with this spirit of exhibition and competition there creeps in the degrading vice of gambling and the chief interest of sports becomes one of speculative betting. Our universities have seriously opposed these tendencies, at least the last generation did so; and now that exercise of various kinds is forming a much more important part of school education than it used to do, it is proper that those who are controlling our games should understand the scientific and moral principles which are important in this part of their work. We have more to say on this subject later on.

THE INSPECTION OF "HIGHER" EXAMINATIONS.

THE question raised last week by Mr. Victor Horsley in regard to the statutory duty of the General Medical Council to inspect the so-called "higher examinations" of the medical Corporations is one of far-reaching importance. It is not one to be decided either by precedent or by opinions, for the matter rests on the interpretation of certain clauses of the Medical Acts, and the construction to be placed thereon must be referred the Council's legal advisers, though their opinion on the subject would not necessarily be conclusive. The matter has not hitherto attracted much attention, probably because it is extremely rare for persons to claim registration on the strength of the diplomas to which such examinations are the passports. Guided by precedent, the President last session ruled out of order a motion by Mr. Victor Horsley calling attention to the alleged insufficiency of the examinations for the fellowship of a particular corporation. Though the ruling was technically correct, inasmuch as the motion embodied statements which were not strictly in accord with the facts, it was construed to mean, and the recent action of the Council confirms that construction, that these examinations are not within the purview of the duties of the Council. The President said that the Council, in abstaining from the inspection of these examinations, has been guided by Section 30 of the Medical Act (1858). This section provides for the registration of "higher or additional qualifications," but of course says nothing about the examinations themselves, so that this point is left The law, however, requires the Council to inspect qualifying examinations, that is to say, examinations which would confer upon the successful candidate the right to claim registration. fellowships of the colleges are expressly mentioned in the official list of registrable diplomas, and there is nothing to prevent a fellow who has neglected to register his membership, or who has gone straight to the fellowship, claiming admission to the Register on the strength of his diploma of Fellow. Indeed, it is within our recollection that a gentleman who had obtained the higher diploma of the Royal College of Physicians of London, practically on the strength of his foreign degree, was admitted to registration, though this was subsequently the subject of discussion which resulted, if we are not mistaken, in the College undertaking not to grant such higher diploma in future to persons not otherwise entitled to be registered. This instance, however, establishes the right of the higher diploma to admission to the Register, and it follows that such examinations are for all practical purposes qualifying examinations. Under these circumstances it is difficult to see how the Council can continue to evade its statutory duty, and it is open to Mr. Horsley to raise the question afresh on more definite lines, and to place the Council on the horns of a dilemma. It is all very well for Sir Christopher Nixon to talk about this or that body refusing inspection. It will be time enough to think about how to enforce the law when the Council have made up its mind to apply it. One rough and ready means suggests itself-viz., to refuse registration of all diplomas of the stiff-necked body until it had bowed the knee.

Rotes on Current Topics.

The General Medical Council and Dispensaries.

THE trial of Dr. Stewart, of Denton, near Manchester, on a charge of covering one Burgess in connection with a certain provident dispensary, marksa further step in the evolution of the Council's views as to what constitutes "covering." The circumstances were peculiar in that the defendant claimed to be merely the paid officer of a dispensary nominally managed by a committee of labouring men who also engaged the dispenser whose conduct constituted the offence. According to the annual report some 28 000. patients were visited at their homes annually in addition to close on 200 surgical operations and about the same number of confinements. Dr. Stewart said he did all this work unaided except in the matter of dispensing, and he formally denied that Burgess ever attended to patients, to his knowledge, or assisted at operations. It is worth noting that on his own showing it was Dr. Stewart's practice to give chloroform and operate himself, often without the presence of a third party, and this even for such an operation as the relief of strangulated umbilical hernia or the removal of a cancerous breast. If true, this statement conveys its own condemnation, but the evidence justifies us in regarding Dr. Stewart's statements with suspicion. Even the figures given above are open to criticism seeing that no books or records of any kind are kept. The question before the Council was whether Dr. Stewart could be held responsible for the conduct of the dispenser, who, with or without Dr. Stewart's knowledge, had certainly visited and treated patients and given chloroform. To find that he was not responsible would evidently open the door wide to the most barefaced violation of the Council's rules on the subject, but, fortunately for the Council and also for the profession, it was easy to arrive at the conclusion that Dr. Stewart could not possibly have been ignorant of his assistant's doings, and if cognisant thereof, he could plainly be justly held responsible therefor. This was the view taken by the Council who found Dr. Stewart guilty of the offence charged against him, but in view of the novelty of the circumstances merely bound him over to come up for judgment in November. It is impossible to exaggerate the importance of this verdict which vindicates professional honesty of purpose, without making Dr. Stewart the scapegoat of a vicious and intolerable state of things. By this decision the Council have made it plain that they are not to be hoodwinked by the manipulation of a few puppets dubbed trustees or managers, and by inference it is laid down that a registered practitioner who associates himself with an institution which is run on unprofessional lines is himself guilty of unprofessional conduct. Although the point was not formally raised in this case it may reasonably be inferred that the Council would consider touting for members to be unprofessional, and this is another step in advance. The decision will clear the atmosphere. It will no longer be open to practitioners to plead ignorance of the views of the Council in the matter, and those who sin in future will do so with full consciousness of the penalties they are incurring.

Prison Vaccination.

A VACCINATION incident that occurred a few weeks since in connection with the Glasgow Prison is worthy of a passing note. It appears that in the course of his duty the Medical Officer of the institution named vaccinated one of the prisoners. The result was an impetiginous arm, and on leaving prison the patient brought an action for £500 damages against the operator. The claim was dismissed both at the original trial and on appeal, chiefly on the ground that the plaintiff had been fully apprised beforehand of the nature of the operation to which he was to be subjected. pursuer, on the other hand, contended that he was led to suppose that the vaccination formed part of the prison discipline, to which he was forced to submit. Under such circumstances it would certainly be wise for the prison surgeon to lay both sides of the case before a prisoner so that there could be no shadow of a doubt as to the legal and voluntary position of both parties to the proposed transaction. As to the unfortunate pus inoculation the accident is not after all said and done a very serious one. It is less and less likely to occur under modern methods, but may occur now and then in the practice of even the most careful surgeon. Certainly where it can be shown that ordinary precaution as to sterilisation of hands and skin surfaces had been observed, there could be no ground of action for malpraxis.

Joint Stock Consultants.

Most of our readers are aware that the system under which third parties farm out the services of practitioners to whom they pay a salary, making a considerable balance of profit, is being now extended to the employment of so-called consultants. This is the "Medical Aid" system, and in Birmingham it is being exploited by no less a personage than Mr. Arthur Chamberlain, but the original inventor of it is a Mr. Bracey, a medical practioner, and connected with the Balsall Heath Dispensary. Four years ago he succeeded in persuading the managers of that institution to appoint seven consultants; these gentlemen agreed to accept half a guinea for a consultation, but do not appear to have devoted their whole time to the work of the dispensary; it seems, however, that Mr. Chamberlain expects that the consultants' whole time will be required by the institution which he proposes, and he offers £500 a year, beside the half guinea fee, to anyone willing to accept the position.

Nothing can be gained, we think, by treating the acceptance of the consultative position as a matter of medical etiquette. Of course, most self-respecting members of the profession will shrink from the proposal that they shall farm out their services for Mr. Arthur Chamberlain or anyone else to make

a profit out of them, still £500 a year, with the prospect of considerable addition from consultation fees, must be too tempting to be resisted by many men, and, in any case, the position cannot be said to be anything less than respectable from a pecuniary point of view. The question settles itself when we consider that a consultant (as the profession understands the term) at half a guinea a visit is an impossibility. The great majority of English patients adhere with confidence to the ministration of their "family doctor" or general practitioner as long as they possibly can, and do not feel the need for a consultant until they are seriously alarmed. When they are seriously alarmed a ten and sixpennny consultant is not what they want. He is cheap but decidedly nasty, and one in fact little better for them than the "family doctor," for whose opinion corroboration or reversal is sought. In such circumstances the patient wants a specialist of long experience and well recognised skill, and the patient will speedily come to learn that he can get nothing but a sort of Jack-of-all-trades by contract for ten and sixpence. Such a "consultant" will do well enough to correct the diagnosis of a general practitioner for the nonce, but, as a judge of final appeal we are certain that the public will have none of him, but, when it must, it will resort to a wellknown specialist and pay him the fee which such an adviser is entitled to expect.

The Bogus Post-Mortem Case.

OUR readers will doubtless remember the curious case which occurred last year, in which a medical man named McKay was charged before Mr. Plowden, the Metropolitan Police Magistrate, with wilful and corrupt perjury at the instance of Mr. Braxton Hicks, the Coroner, in connection with certain evidence which had been given before him at an inquest. Briefly recapitulated it was alleged that McKay had sworn to having made a careful examination of the brain and viscera whereas, according to the evidence of the police surgeon, who, on the Coroner's order, made a subsequent examination of the body, no real post-mortem had ever been made. Recalled examination before the coroner, and confronted with this evidence McKay blindly adhered to his previous statements, whereupon the Coroner ordered him to be charged with perjury. Mr. Plowden, whose behaviour throughout the hearing of the case was characterised by extreme discourtesy and flippancy, laughed the case out of court on the ground that it was merely a question of a difference of opinion between two doctors. We commented on the case at the time, and the result of the trial, which took place before the General Medical Council on Thursday last, amply justifies the views we then put forward. Mr. McKay was charged before his peers with having failed to make the examination required of him and with having falsely sworn contrary to the facts. The evidence was overwhelming. indeed the defendant had absolutely no defence to

offer, and the conduct which Mr. Plowden thought so lightly of has been adjudged by a full Council to be "infamous," and to merit the erasure of his name from the Register. There is no more responsible duty thrown upon the medical practitioner than the making of post-mortem examinations, and it is difficult to qualify, as it deserves, the conduct of a practitioner who deliberately swears to statements which he has not taken the trouble to verify, with the result that the evidence which he gave was positively misleading.

Sir George Pilkington, M.P.

The new member for Southport is a member of our profession, and has seen something of hospital and private practice when he was a surgeon to the Southport Infirmary. His original name was Coombe, and he is the son of Dr. Coombe who practised at Upwell in Cambridgeshire, but he assumed the name of Pilkington and the estates held by Mr. James Pilkington who, for nineteen years, represented Blackburn in the Liberal interest. Sir George holds the diplomas of the London "College and Hall" of the year 1870, and he has served as Mayor of Southport, and in many other public capacities.

Smoking in Theatres.

It is reported that the Theatrical Managers' Association are desirous of introducing the privilege of smoking into theatres, and obtaining the sanction of the Lord Chamberlain to this innovation. public official has power to make regulations for the safety and comfort of the audience, and in the exercise of his discretion he has generally prohibited smoking. We trust that this prohibition will be continued, the Theatrical Managers Association notwithstanding. A member of the latter body has said. "I am certain of this that the first West End theatre which gives a light entertainment and permits smoking in the auditorium will make a big fortune." Quite possibly this might prove to be the case, but "a light entertainment" which could only be made attractive by permitting the audience to smoke, is scarcely likely, we think, to become a popular feature among the theatre-going public who know the difference between a theatre and a music-It may be quite true that the habit of smoking in their presence is not resented in the present day by ladies, but it does not follow that because such tolerance has been acquired by custom, that the health of our wives and daughters is improved by allowing them to expose themselves to a atmosphere reeking of tobacco smoke when in search of amusement. The ventilation of most theatres, especially in hot weather, is bad enough as it is, but if, to the already bad hygienic conditions, smoking be added, then the theatre, as a source of amusement, will become a place to avoid. We submit that in the interests of the health of the public who patronise theatres the proposed innovation would be distinctly A good play does not require the subject.

stimulus of a pipe, a cigar, or a cigarette to make it interesting; on the other hand, a music hall entertainment can seldom be tolerated without one or the other. To endeavour, therefore, to convert a theatre into a music hall, and to lower the standard of the entertainment of the former so as to bring it to the same level as the latter, appears to us to be a questionable policy for the Theatrical Managers' Association to pursue, apart from the other considerations which we have named.

More Bones in Southwark.

METROPOLITAN Southwark appears to be fated to intermittent public commotions in the matter of its ancient burial grounds. It is not many months ago that St. George's, Southwark, was made a nine days' wonder by reason of an order issued from the Home Office to remove and bury elsewhere the remains of some two thousand parishioners whose bodies had been interred in the crypt of the parish church. By the way, it is interesting to learn that the work of removal has not yet been commenced, although ten months have sped by since the the departmental order. issue of Now, the neighbouring parish of St. Olave's, Southwark, has got up another little scandal of its own. The Bishop of Southwark, wishing to clear the bones out of a certain church, secured the co-operation of Dr. Bond, medical officer of health, and proceeded without further parley to effect the clearance. Whether or not his lordship had previously secured the sanction of the Ecclesiastical Commissioners we cannot say. The matter got wind, however, and unsparing public comment, both official and journalistic, thereupon became the order of the day. The Vestry have suspended the medical officer of health, an extreme step that will necessitate an inquiry by the Local Government Board. Whatever the rights of the case may be, it seems hardly wise for a public official to commit himself to private action in a matter so technical and hedged in by legal safeguards and difficulties as the clearance of a burial place. History has abundantly demonstrated, moreover, that the episcopal ardour is apt to lead to legal complication. The Bishop of Rochester, to whom His Lordship acts as suffragan, has since closed the Church, so that what with the indignation of the public and the apparent neglect of legal forms, there is every prospect of a rapid thickening of a somewhat sensational plot.

Specialism in Excelsis!

At the meeting of the American Medical Association which takes place on the 6th inst. at Columbus, there is to be a section devoted to proctology, an euphonious term to designate practitioners (or shall we say proctitioners?) who make the rectum their special study. We will make bold to say that the proceedings in this section will be much more seemly than in the Ethical Section of the British Medical Association, in spite of the uninviting nature of the subject.

The Prohibition of Indiscriminate Kissing. It has been found nece ssary in certain parts of the United States to direct the attention of the legislatures to the desirability of prohibiting indiscriminate kissing, not, it would appear, in the interests of public morality or in deference to the susceptibilities of the American Mrs. Grundy, but with the view of checking the spread of tuberculosis. the tubercle bacillus must possess unaccustomed virulence in the Western hemisphere or else the kissing that goes on there must be unduly, indeed, unneces sarily, prolonged. Kissing, even indiscriminate, has not been included by Sir Richard Thorne-Thorne among recognised factors in the spread of tuberculosis. Assuming the accuracy of the allegation, we may point out that it is one thing to prohibit indiscriminate kissing, and another to enforce the veto. It would have to be a conditional veto, that is to say, no young person would be allowed to indulge in promiscuous kissing until he or she failed to react to the tuberculin test for the disease, and even then the written consent of the parents might be insisted upon, duly authenticated by the nearest parson or magistrate. With singular lack of good taste, the memorialists have coupled with this representation the expression of a desire to restrict spitting in public places, as though the two nuisances (?) had anything in common.

Nicholas Senn, M.D., LL.D.

DR. NICHOLAS SENN, of Chicago, has been accorded the honorary degree of Doctor of Laws by the Trustees of Jefferson Medical College. Is it not about time this farce of conferring honorary degrees was abandoned by all self-respecting universities? We speak with bated breath, seeing that our own universities are still absurdly generous with such titular distinctions, and even appear to take pleasure in exaggerating the absurdity of the practice That a physician or surgeon should be made an honorary Fellow of his College is reasonable enough when his professional status seems to call for official recognition, but to make a medical man who is obviously a stranger to law, a doctor of that ilk is about as absurd as to make a princess a Doctor of Music. A degree either means something or nothing, and if the latter it is surely unwise to call attention to the fact, thereby sapping the esteem which University degrees still attract among the unlearned.

The New Vaccination Act.

The anti-vaccinationists who imagined that Mr. Balfour's surrender of compulsory vaccination had placed the game in their own hands have had a sharp reminder that unrevoked law holds good in this country. Last week in the House of Commons a member moved the reduction of the Local Government Board supply because vaccination inspection generally had been directed to enforce prosecutions without regard to the particular views of local boards of guardians. In reply, Mr. Chaplin proclaimed himself a firm advocate of vaccination and declined to withdraw the circular of which complaint had been

made. The gist of the document is that defaulters should be prosecuted by the inspectors without waiting for directions from their boards. That is to say, the officials mentioned are to proceed as they have always done under untouched provisions of former Acts. The position of anti-vaccinationist members is not clear. They have gained the enormous concession of conscientious objection, and now they seem to think that the new principle involved should free persons who are too careless to avail themselves of that method of evading the obligation to vaccinate. Reduced to a plain statement, Mr. Pickersgill and his brother anti-vaccinationists are making a deliberate attempt to override the law of the realm, and to convert their inch of privilege into an ell of illegality. It is a way of the sect to pose as injured martyrs, and we hope to deal at length with some of their arguments in an early issue.

The New Medical Staff of the Seamen's Hospital Society.

THE Seamen's Hospital Society have, it is true, succeeded in filling the vacancies on the medical staff of their hospital created by the resignation of the well-known physicians and surgeons which took place some weeks ago, but that is practically all that can be said upon the matter. As a protest to the treatment which the late staff received the appointments have clearly been left severely alone by physicians and surgeons of acknowledged position, for otherwise the names of well-known consultants would have figured upon the list of the new staff. We are glad that in this respect the committee of the Seamen's Hospital have been taught a lesson. The members of their late staff were all well-known members of the profession, for the most part attached to important hospitals in London—the same cannot be said of those whose services have just been secured to fill the vacancies. There has, therefore, been a distinct loss of prestige in the transaction, which might never have occurred had the committee in question acted with that politeness and consideration to their late staff such as the latter were at least entitled to expect.

The Typhoid Epidemic in Philadelphia.

"AFTER an epidemic of typhoid fever of shameful proportions and duration," says the New York Medical Record, "in the course of which some thousand lives have been sacrificed, the authorities of Philadelphia have ordered an investigation of the water supply of that city." There are evidently some things which they do not do better in the States, or at any rate in Philadelphia, In this country any undue prevalence of typhoid fever promptly attracts official attention, and the district is pounced upon by a Local Government Board Inspector, who gives wiggings where wiggings are due-and then, as often as not, things go on ut ante. We note that this is the moment the citizens of Philadelphia have chosen to petition the Mayor for "a quiet Sunday." If this epidemic be allowed to proceed unchecked we shall soon have the silence of the grave, and the city

will cease to have any but an etymological claim to its name.

The Royal Orthopædic Hospital.

THE dispute at the above hospital raises in a pointed form the whole question of the management of the medical charities. It is, of course, known to everyone that the interest of the average subscriber to the hospitals ends with the payment of his donation. The result is that the management is apt to drift entirely into the hands of a few persons, who may or may not be models of probity and good judgment. While as a general rule we condemn utterly the manufacture of "faggot" votes it must not be forgotten that under such circumstances it may be the only weapon wherewith to fight an obviously corrupt or faulty governing board. In advancing this view we do not for a moment reflect on the good faith of the committee that has hitherto administered this particular hospital, which is obviously above and beyond suspicion. At the same time the right of the governors of a hospital to manage affairs in their own way is indisputable, and no system that fails to provide for a free election of management can claim to be on a satisfactory basis. The party until lately in power at the Orthopædic Hospital are bringing forward a new rule to exclude members of the honorary staff from the executive committee. To attempt to exclude members of the staff because they hold differing views is, in our opinion, the most damning method of argument that could be brought forward by Sir Walter Gilbey. So far from that course being desirable, we would make the whole staff ex officio members of executive, and add to their number outside general practitioners. It is only by such a leaven that any hospital can hope to be in touch with the wants, the wishes, and the aspirations of the medical profession at large, interests that are now too often ridden over roughshod.

Typhus Fever in London.

WE learn from the New York Medical Record that typhus fever has been mildly epidemic in London during the past winter, the diagnosis having apparently only recently been made, most of the cases having been returned as typhoid, pneumonia, or influenza. There is some excuse for the non recognition of the disease by the British medical practitioner, because not one in a thousand, even if in large practice, have ever been privileged to see a case of typhus, either in hospital or outside. This is just one of the diseases that might advantageously be made the subject of post-graduate lectures, illustrated by artificially coloured wax models to show the eruption. Post-graduate institutions, please note!

Unvaccinated Camp Followers.

THE War Office has intimated that the health of troops cannot be allowed to be imperilled by the introduction into their barracks of the unvaccinated wives and children of soldiers. Such persons will, therefore, have to live outside until they have been vaccinated, and they will not, in future, be carried to foreign stations at public expense.

The Elections at the Irish College of Surgeons-THE annual election of the President, Vice-President, and Council of the College came off on Monday last, as fixed by the Charter. For the firstnamed offices there was no contest, as it is the custom of the College that the President and Vice-President shall serve for two years, and Mr. Robert L. Swan and Mr. T. Myles were accordingly re-elected nem. dis. The secretary of the College, Sir Charles Cameron, was also re-elected, this office being practically permanent. As regards the Vice-Presidency of next year (June-1900), which will be vacated by Mr. Myles on his promotion to the presidential chair, the interest is centred upon the contest for the honour between Mr. Lambert Hepenstal Ormsby, Surgeon to the Meath Hospital, and Mr. Francis T. Heuston, Surgeon to the Adelaide, whose respective claims, as far as can be judged at present, seem to be pretty equally supported by the Fellows. Already the canvass for votes is in active progress. For election to the 19 seats on the Council of the College, 24 Fellows offered themselves. All the outgoing Council were candidates, but Mr. Henry Gray Croly and Mr. Arthur Benson had left a hiatus by the recent election of the former as an Examiner in Surgery, and the retirement of the latter. Of the retiring Council all were re-elected except Mr. Arthur Chance, of the Mater Misericordia Hospital. Mr-William Stoker, professor of surgery in the college, and Mr. John B. Story, of St Mark's Ophthalmic Hospital, and Mr. Richard Bolton MacCausland, of Stevens's Hospital, secured the three open seats. The total poll (which is taken by ballot papers) was 225 out of a possible 290 Fellows.

The Irish Medical Association.

THE Committee of Council met in the Royal College of Surgeons of Ireland last week and completed arrangements for the annual meeting, to be held in Cork on June 20th. Efforts are being made to obtain the consent of the railway companies togrant to members attending the meeting return tickets at single fares. The resolutions to be proposed at the meeting were considered and approved. The commentary on the Local Government Board rules for the government of dispensary districts was under consideration, and will be issued to members during the present week.

The Birthday Honours.

The 80th birthday of the Queen has been marked, contrary to the general anticipation, by a scant array of honours. The medical profession, however, enjoys a good share in the published list. First and foremost comes a baronetcy for Dr. Burdon Sanderson, who has been a distinguished member of the profession for over fifty years. He is Regius Professor of Medicine at Oxford, and before taking that post held the Waynflete Professorship of Physiology in that University. His name is known throughout the scientific world, and no man is more deserving of honour. In the sister University of Cambridge physiology is further recognised by the conferring of the title of K.C.B. on

Professor Michael Foster, who is also Secretary of the Royal Society. His contributions to embryology and other branches of physiological research are many and famous. In Liverpool Dr. Mitchell Banks, the genial and accomplished surgeon, and in Edinburgh Dr. John Sibbald, the lunacy expert and commissioner, have each received a well-earned K.C.B. Surgeon-General Albert A. Gore, late Principal Medical Officer in India, is made a C.B. (military division), and Major Baptie, R.A.M.C., a C.M.G.

Pharmaceutic Judges.

In a recent suit in the Scotch Courts an interesting lega! point arose which brought the case to a dead lock. The Scotch law forbids a judge to adjudicate in the case of a company in which he holds shares. This particular suit had to do with the system of dispensing by unqualified persons under cover of a qualified pharmaceutist. There are thirteen judges of the Court of Session, and, of these every man was a shareholder in the company, and, therefore, there was no court to try the case until, by compromise, it was agreed between the litigants that the verdict of one of these judges be taken as sufficient.

PERSONAL.

It affords us pleasure to announce that the health of Sir Francis Laking, M.D., has greatly improved during the last few days, and that the serious symptoms have subsided.

Mr. John Shaw, of Wakefield, who died last week, has bequeathed £2,000 to the Wakefield-Clayton Hospital and the residue of his estate which is expected to amount to at least £50,000.

WE understand that Major Arthur W.P. Inman, of the Army Medical Corps, has been appointed to succeed Dr. William Carte, as Surgeon to the Royal Hospital at Kilmainham (Dublin).

DR. G. GRANVILLE BANTOCK, of London, has been elected by the "Société d' Obstetrique de Gynæcologie et de Pediatrie de Paris," "Membre Associe Etranger, Section de Gynecologie."

We regret to learn that Dr. Sinclair Coghill, who only returned from the Berlin Congress on Tuberculosis on Friday last, at which he read a paper, was seized with suden illness at his home, Ventnor, and died on Monday.

Dr. Apostoli, of Paris, is, we understand, engaged in writing a chapter on the uses of electricity in gynecology for the third edition of Dr. Althaus's work on "The Value of Electrical Treatment," which will embody his most recent experience in the electrical treatment of uterine disease.

CAPT. NEUMANN, the Indian Plague expert engaged by the Natal Government, has, says our South African correspondent, given an opinion that there is little danger of an actual epidemic of plague in South Africa. He has urged the Government to obtain an ample supply of Haffkine's serum, which he regards as most valuable.

Scotland.

[FROM OUR OWN CORRESPONDENT.]

University Medico-Chirurgical Society.-An extraordinary meeting of this Society was held on the 24th ult. to hear a lecture by Dr. Lawrence, of Montrose, on "Some Reminiscences of the Glasgow Medical Schools in the Thirties." There was a large attendance of students, including a considerable number of ladies from Queen Margaret College. The lecturer described in an interesting manner the condition of things as regards medical tuition existing in the thirties in the two extra-mural schools, viz., Anderson's University (now Anderson's College) and Portland Street Medical School; at that time these two schools possessed as teachers many men of eminence. He referred to the controversy on bloodletting, which began in 1847 and continued for many years, this practice during his time of study was the recognised and unchallenged treatment of all inflammatory diseases. The only infirmary in Glasgow at that time was the Glasgow Royal Infirmary which was attended by all the students, the classes being open to all interested without an entrance examination, the "amateur" medicals mixing with the regular students, and among the latter many appeared ill-prepared for such a course of study, in which connection Dr. Lawrence (the lecturer) bore testimony to the benefit of the Medical Act of 1858, which necessitated a preliminary examination before entering on a course of medical study.

GLASGOW UNIVERSITY.—The final examinations are now in full swing; the students are, however, complaining of the length of time over which the clinicals extend, owing to the fact that these have to take place entirely in the Western Infirmary; this cause for grumbling seems, however, likely to be soon overcome, as it is intended to send a part of the students for clinical examination to the Royal Infirmary, a part to the Victoria Infirmary, and the remaining part to the Western Infirmary. As Professor Sir William T. Gairdner is at present in London attending the General Medical Council, Professor Stockman is conducting the examination in Clinical Medicine. During the winter session it is said that much hard work was done not only by the students but by the professors, consequently at the close both parties were very much forced.

both parties were very much fagged.
HEALTH DEPARTMENT, GLASGOW.

HEALTH DEPARTMENT, GLASGOW.—A salary of £350 per annum is to be paid to the Bacteriologist to the Health Department, who must devote the whole of his time to the duties of his office, and be able to undertake chemical, microscopical, bacteriological examination, and analysis of water, air, soil, milk, tuberculous meat, diseased tissues, and pathological substances. For this appointment an advertisement is to be inserted in certain Scottish, English, and German newspapers. It would have been more complete to have said "several Continental newspapers."

Correspondence,

We do not hold ourselvee responsible for the opinions of our correspondents,

ENGLISH v. FOREIGN OPHTHALMIC SURGERY.
To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—It is probable that some correction will be made of the statement in the Sunday Sun that Dr. Pagenstacher is the son of the celebrated oculist, who died from an accident some years ago. It seems that there is more interest taken now in matters medical by the Press than was the case at one time, but that interest is not always such as one can admire. The chief purpose, however, of this letter is to ask whether there is any good reason for the opinion that this great metropolis is not so well supplied with knowledge of the science and skill in the practice of ophthalmics as some other countries are. Is it because the profession generally does not recognise the neces-

sity of something more than a knowledge of common surgery by those who take up as a specialty the treatment of diseases of the eye? When we consider to what extent the science of optics should be studied by those who follow this branch of practice, and when we see little evidence of this being done, perhaps because we are most of us so ignorant of the science ourselves, we ought not to be surprised that the public, among whom there is some intelligence and appreciation of excellence, should go where they can find what they imagine is unobtainable at home. If such a specialty as ophthalmic surgery is followed for the sole purpose of what is generally termed "making money," there are some of us who may not regret that this should be corrected. et that this shows truly,
I am, sir, yours truly,
PRESBYOPIA.

June 5th, 1899.

THE SPECTACLE MAKERS' DIPLOMA.

To the Editor of THE MEDICAL PRESS AND CIRCULAR. SIR,-Your editorial on the subject of "certificated opticians" rather seems to throw cold water where warm and solid support is needed. The granting of certificates to these persons amounted to the opening up of another branch of unqualified practice, nothing more and nothing less. What does a man like Professor Silvanus Thompson, urbane and accomplished though he be, know or care about the wants and wishes of the medical profession, of which body he is not a member. He has, on the other hand, beyond a doubt solid reasons for becoming an examiner of the Spectacle-makers' Court. But what of those within our own gate? Dr. Lindsay Johnson is also an examiner.

It is possible the medical profession can do little by way of showing their disapproval of his action; it seems likely, also, that the General Medical Council can and will do nothing; but how about the Ophthalmological Society, of which Dr. Johnson is a more or less prominent member. What steps have that learned body taken to justify or to condemn Dr. Johnson's position? It seems to me, as a humble general practitioner, that the profession has a right to demand a full and immediate answer from the Ophthalmological Society.

I am, Sir, yours truly,

A Qualified Onlooker. Croydon, June 2nd, 1899.

THE MEDICAL APPOINTMENTS TO THE BRADFORD WORKHOUSE.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR, -The whole profession owes a debt of gratitude to THE MEDICAL PRESS AND CIRCULAR for its defence of our rights and privileges, and for its advocacy of proper principles in the election of Poor-law Medical Officers. And not for the first time have you adopted this impartial and independent attitude.

In reference to the recent appointments to our workhouse, in which both the Guardians and two gentlemen representing themselves as consultants, have played a role as novel as it is wrong in every sense, I ask to be allowed to reply to the defence of the two medical offenders. Dr. Crowley and Mr. B. Hall have attempted to excuse themselves, and minimise the gravity of the position they have adopted in hostility to the whole profession here, by an amusing artifice—so simple, however, in its nature, that probably most of the readers of your able criticism of it hardly need to have it pointed out. Dr. Crowley and Mr. Hall would have it believed that I constitute the opposition to their unprofessional conduct; that I have forcibly dragged together a number of gentlemen who have unwillingly condemned their conduct, and that other professional men and societies in Bradford, by not publicly disapproving, have approved of what they have done! This device is really too amusing! Had I the vast power they attribute to me, then do they not see that my opposition to their proceedings would be a very serious matter? Yet, though crediting me with the ability to drag the profession at my heels, they immediately proceed to argue that I am an alto-gether insignificant person! As a fact, they do not offer one argument in their own defence. They cannot. All

they do is to indulge in personalities directed against myself, and to try to minimise the importance of the indignation meeting which condemned their action. me this is most gratifying. It is the strongest proof of the excellence of our cause, and of the indefensible action of Dr. Crowley and Mr. Hall. It amounts to this: "We cannot defend our taking these appointments, so let us not attempt to do it, but let us abuse Dr. Hime, and belittle the indignation meeting!" What have I, or that meeting, to say to the propriety of Dr. Crowley and Mr. Hall supporting the guardians in a line of action which is insulting to every general practitioner in Bradford, which is exceptional in character, and is utterly opposed to the fair and honest principles which have so far made all public appointments open to general competition, instead of being allocated by private favour and secret treaty, as in the case of Dr. Crowley and Mr. Hall? If no meeting had been held, if I did not exist, their action would be no less reprehensible.

But what are the trivial assertions they do make when attacking me, and endeavouring to undervalue the

medical meeting?

 "The meeting was not representative." Representative of what? only medical men were there. All our hospitals were represented, all our medical societies were represented, private practitioners, Poor-law medical officers, residents in the city and district, all were there-The only parties not represented were Dr. Crowley and Mr. Hall, who, for reasons best known to themselves, were conspicuous by their absence. There and then was the occasion for them to meet their professional brethren. They preferred not to do so. And yet they are courageous enough to make unwarranted statements about what took place at the meeting.

2. "Invitations were in several cases omitted." There were 148 circulars issued, and I believe some 120 medical men live in Bradford. If anyone was passed over it was owing to accident or to his name not being in the

Directory.

3. "The majority of practitioners of any position took no part in the proceedings." As chairman of the meeting, I can say this is quite contrary to the fact. The discussion was as general as could be desired, or is usual, and not one person opposed the resolution condemning the action of Dr. Crowley and Mr. Hall.

4. As to the influence and importance of the Bradford and West Riding Medical Union I need say nothing. is not in any way concerned in the unprofessional actions of Dr. Crowley and Mr. Hall. The indignation meeting was not a gathering of any society, but was a large meeting summoned by invitation issued to every medical man in the district. As no private individual could assume the right to summon such a meeting, and there was not time to get a requisition signed, the secretaries of the Bradford and West Riding Medical Union were instructed to issue the invitations. I was elected to the

chair by the meeting itself.
5. "The committee of the Medico-Ethical Society (an older society than the Union) after discussion of the action of Dr. Crowley and Mr. Hall, decided to take no action." In assuming that this decision implies approval, or that the members one and all do not condemn their action, Dr. Crowley and Mr. Hall are deceiving them-selves, and attempting to deceive your readers. The fact, as I am informed on the best authority, is that as it was known the Union had decided to take action, the committee of the other society thought it unnecessary to move. But there is no justification for the assumption that their inaction implies any approval, or even neutrality on the question at issue.

I have never known equal unanimity on any question among medical men in this town, and I imagine that though Dr Crowley and Mr. Hall try to whistle cheerfully, their conviction is they have made a serious blunder.

I am, Sir, yours truly, John Whiteside Hime.

On account of great pressure on our space owing to the session of the General Medical Council, and other matters of current moment, we have been reluctantly compelled to omit a large portion of Dr. Hime's letter, but the foregoing contains all the chief points.—ED.]

Obituary.

NORMAN KERR, M.D., C.M.Glasg., F.L.S.
It is with much regret that we have to record the death of Dr. Norman Kerr, which took place at his residence in Hastings on the 30th ult. The temperance cause, of which he was the most staunch, consistent, and enlightened advocate, will be a great loser by his death, for the reputation which he enjoyed in this regard was world-wide. Again, the good influence which he wielded in advancing the principles of teetotalism was by no means confined to this country; throughout Europe, in America, and our colonies his name was a household word among those who sought to fellow his teaching and example. Dr. Kerr was a native of Scotland, and received his medical education at the University of Glasgow, where he took the degrees of M.D. and C.M. in the year 1861. From an early period in his career he began to devote himself to the study of inebriety, and having thus started upon his life work his enthusiasm for it never failed even to the end. As late as April last, feeling somewhat stronger, he journeyed from Hastings in order to take the chair at the quarterly meeting of the Society for the Study of Inebriety in London. This, we believe, was the last time that he was able to undertake any public duty. In the course of last year his failing health compelled him to relinquish his practice in St. John's Wood, where he had resided for many years, and move to Hastings. The illness from which for some months previously he had been suffering was albuminuria, and the quiet, rest, and change of air which he obtained at Hastings proved for a time so beneficial that his health greatly improved. However, an attack of influenza, followed by bronchitis, proved too much for his failing strength, and he gradually sank and died, as stated, on the 30th ult.

At the time of his death he was consulting physician to the Dalrymple Home for Inebriates, President of the Society for the study of Inebriety, Chairman of the Inebriates' Legislation Committee of the British Medical Association, and a member of the Council of the Metropolitan Counties branch, a Fellow of the Linnean Society, and a corresponding member of other societies in New York. Dr. Kerr was a voluminous writer upon his special subject, as may be gathered from the perusal of the long list of his published works. Perhaps his best known work is his treatise on "Inebriety; its Etiology, Pathology, Treatment, and Jurisprudence," the third edition of which appeared in 1894. He was also a frequent contributor to the medical journals, in which he published many thoughtful papers.

But in paying this small tribute to one who, a quarter of a century ago, was a subscriber and staunch friend to THE MEDICAL PRESS AND CIRCULAR, we cannot conclude without expressing our admiration for the earnestness and singleness of purpose with which Dr. Norman Kerr's advocacy of teetotalism was always distinguished. He could not fail to impress those with whom he was intimately associated that his great desire was to leave the world better than he found it by warning his fellow mortals against the evils and pitfalls of alcohol. He laboured and strove, not for his own ends, but with the

sole aim of disseminating the principles in which he firmly believed, in order that others might benefit from their practice. That such advocacy as his was productive of good and that he attained by its means his object in life, cannot admit of dispute. Dr. Norman Kerr was in his sixty-sixth year at the time of his death.

The Medico-Psychological Association.

THE next examination for the certificate of this Association will be held on July 13th at the various centres in England, Ireland, and Scotland. The examination for the Gaskell Prize will be held in London on July 14th. Particulars of these examinations will be found in our advertisement columns.

Medical Aews.

The Royal British Nurses' Association.

H.R.H. THE PRINCESS CHRISTIAN has announced her intention of presiding at the annual meeting of the Royal British Nurses' Association and of presenting badges to members on that occasion. The meeting will be held at the Westminster Town Hall, on Saturday, June 10th, at 3 pm., and will be followed by a reus os of members and their friends in the grounds of the Earl's Court Exhibition. Full particulars and tickets may be obtained from the Secretary, 17, Old Cavendish Street, Oxford Street, W.

Society, for Relief of Widows and Orphans of Medical Men.

THE annual general meeting of the Society was held on May 31st, Mr. Christopher Heath, V.P., in the chair. From the report read by the secretary, it appeared that a sum of £3,023 had been given during 1898 to the fifty widows and twelve orphans in receipt of grants and the six recipients from the Copeland Fund. A present of £551 had been made at Christmas—viz., £10 to each widow, £3 to each orphan, and £5 to those on the Copeland Fund. One widow had died and one was taken on, three orphans had become ineligible and one had been elected. The number of members remained the same— 287, nine having died, and nine been elected. The expenses of the year had been £244 10s., the total disbursements £3,267 10s., and the receipts available for payments £3,326 2s. 8d., leaving a balance of £58 12s. 8d. A grant under bye-law 78 of £26 was made to a widow. A vote of thanks to the Editors of the Medical Journals, proposed by Mr. Lynch and seconded by Sir Samuel Wilks, was carried unanimously. Sir Thomas Smith was elected a Vice-President in the place of Mr. Henry Lee, deceased, and Messrs. Morey, King, Grimson and Leigh, Dr. West and Dr. Whipham directors, in the place of the six seniors who retired. The funded property had been increased by purchase of 2500 Birmingham 2½ per Cent. Corporation Stock. The funded property of the Society on May 1st, 1899, was 297,687 15s. 11d. The proceedings terminated by a vote of thanks to the Chairman, proposed by Mr. Lovett and seconded by Dr. Pollock.

St. Thomas s Hospital.

The following gentlemen have been selected as

House Officers from Tuesday, June 6th, 1899:—
House Physicians: E. H. Ross, L.R.C.P., M.R.C.S.;
E. A. Gates, L.R.C.P., M.R.C.S. (extension); A. E. Stevens, M.B.Durh, L.R.C.P., M.R.C.S. (extension); and H. C. Thorp, M.A., M.B., B.C.Camb.

Assistant House Physicians: J. Ga M.R.C.S., and A. Bevan, L.R.C.P., M.R.C.S. Gaff, L.R.C.P.,

House Surgeons (extension): S.O. Bingham, L.R.C.P., M.R.C.S.; E. M. Corner, M.A., M.B., B.C.Camb., B.Sc. Lond., L.R.C.P., M.R.C.S.; J. A. Barnes, L.R.C.P., M.R.C.S., and J. E. Kilvert, L.R.C.P., M.R.C.S.

Assistant House Surgeons (extension): H. J. Phillips, L.R.C.P., M.R.C.S.; P. W. G. Sargent, M.A., M.B., B.C.Camb., L.R.C.P., M.R.C.S.; S. A. Lucas, L.R.C.P., M.R.C.S. and H. T. D. Acland, L.R.C.P., M.R.C.S.

Obstetric House Physicians (senior): S. H. Belfrage, M.B.Lond., L.R.C.P., M.R.C.S., and (junior) H. M. Scaping, B.A.Camb., L.R.C.P., M.R.C.S.

Clinical Assistants in the Special Department for Diseases of the Throat: E C. Bourdas, L.R.C.P., M.R.C.S. (extension), and L. H. Lindley, M.B., B Ch. Oxon. Skin: H. R. Beale, L.R.C.P., M.R.C.S., and N. Unsworth, L.R.C.P., M.R.C.S. Ear: A. W. Jones, L.R.C.P., M.R.C.S. (extension), and A. C. Bird, L.R.C.P., M.R.C.S. M.R.C.S.

Society of Arothecaries of London.

THE following candidates passed in the subjects indi-THE following candidates passed in the subjects indicated during May:—
Surgery.—G. H. Bedford, P. Cator, T. A. E. Fawcett, A. Killick, D. V. Lowndes. A. Orme, V. S. Partridge, W. Sisam, J. M. Twenty, man R. Le G. Worsley.
Medicine.—E. L. D. Dewdney, R. F. Ellery, T. A. E. Fawcett, A. Orme, O. C. Sibley, W. Sisam, H. E. Weston.
Forsenic Medicine.—E. L. D. Dewdney, S. H. Longhurst, A. Orme, O. C. Sibley, H. E. Weston.
Midwifery.—T. Burdekin, A. F. Carlyon, W. J. H. Hepworth, T. E. Holman, H. N. Horton, A. Kıllıck, W. Sisam, F. J. Waldmeier.

JUNCKER AND STAHL'S THEORIES.

To the Editor of the MEDICAL PRESS AND CIRCULAR.

Sire,—The book your correspondent refers to is that of John Juncker, which was published first in 1718, consisting of 752 4to pages. The author was a pupil of George Ernest Stahl and a voluminous writer. Stahl became a disciple of Descartes, and, dissatisfied with the intro-mathematical theory of Giovanni Borelli, he introduced the doctrine of the influence of immaterial principles on inert substances.

inert substances.

Stahl taught that a principle resident in the living body (animo) governed all the functions of life and resisted putrefaction. He supposes the snima to have knowledge of the necessary composition of every part of the body and of the materials to be given to each, and to have power to guide aright all the acts recessary to the desired end. The vital principle and the nature of medical writers differs but in name from the anima of Stahl.

For the relief of plethora he bled, and his principal remedy was a mild confident.

For the relief of plethora he bled, and his principal remedy was a mild aperient.

Juncker's work, 4to, 1718, is entitled "Conspectus medicine theoretico-practices, tabulis exvi omnes primarios morbus, methodo Stahlaini tractandos, exhibens; cum indice satis locuplete et piefatione....Stahlu."

In all he published ten volumes, all intended to explain and support Stahl's views.

In all he published ten volumes, all intended to explain and support Stahl's views.

His works were, however, discounted by Baron Haller's brief account of Stahl's doctrines, and the summary of them that appears in Sprengel's "Histoire de la Medicine," tom. v.

As late as 1708, Stahl published his "Theoris Medica vera Physiologiam et Pathologiam tanquam Doctrine Medicæ partes contemplativos et Naturæ et Artis veris Fundam entis intaminata Batione et in concurrar experentia, distens."

His theory of phlogiston is told in his "Zymotechnia Fundamentalis," in 1637.

Juncker's works are now little read; indeed, they never seem to have got beyond the first edition, and your correspondent would not get more than 5s, for the volume. One penny a volume is the usual bookstall price of old medical works.

I am, Sir, yours truly,

Dublin.

N. B. T.—No information has reached us so far which bears out

N. B. T.—No information has reached us so far which bears out our correspondent's complaint.

OMEGA.—If our correspondent will forward the newspaper cuttings relating to his statements we shall be glad to deal with the matter. Young M.D.—There is nothing to take exception to, from an athical point of view, in the course pursued.

A CASE FOR TREATMENT.

A CORRESPONDENT writes: "I should be glad of some hints for the treatment of a patient, a girl, aged 18, who is troubled with nocturnal incontinence of urine. Extract of belladonna for a time proved useful, and tonics, but now she is as bad as before. Could any of your readers kindly help me?"

Meetings of the Societies and Tectures.

WEDNESDAY, JUNE 7TH.

OBSTETEICAL SOCIETY OF LONDON.—8 p.m. Specimens will be shown by Mr. Stott, Mr. Malcolm, Dr. Stevens, and others. Papers:
—Dr. Lewers: A Case of Persistent Mento-posterior Position of the Face in which the Child was delivered Alive by the Aris-traction Forceps. Dr. Wilson: Hydramnion in Cases of Uniovial or Homo-Forceps. Dr. logous Twins. THURSDAY, JUNE 8TH.

THURSDAY, JUNE STH.

OPHTHALMOLOGICAL SOCIETY OF THE UNITED KINGDON.—8 p.m. Cases and Specimens. 8.30 p.m. Papers:—Dr. Rockliffe and Mr. Hainworth: Penetrating Wound of Orbit with Traumatic Meningitis, Recovery.—Dr. Beevor and Mr. M. Gunn: Case of Obliteration of a Branch of the Retinal Artery, following frequent attacks of Temporary Amblyopia.—Mr. J. B. Story: Recovery of Sight after Partial Occlusion of the Central Artery.

BRITISH GYNECOLOGICAL SOCIETY (20 Hanover Square, W.)—8 p.m. Lautern Demonstration: Dr. F. W. N. Haultain (Edinburgh): On a Case of Deciduoma Malignum. Papers:—Dr. Mendes de Leon (Amsterdam): On General Disorders originating in disease of the Female Pelvic Organs.

CENTRAL LONDON TREOAT, NOSE, AND EAR HOSPITAL (Gray's Inn Road).—5 p.m. Dr. Dundas Grant on the Diagnosis and Treatment of Painful Ear Affections.

FRIDAY. June 9TH.

FRIDAY, JUNE 9TH.

BENGER'S

GOLD MEDAL AWARDED

Health Exhibition, London.

FOR INFANTS, INVALIDS, FOOD.

This delicious highly nutritive and most easily digested Food is specially prepared for Infants, and for those whose digestive powers have been weakened by illness or age.

The following letter addressed to F. B. BENGER & CO., Ltd., is published by special permission of the Russian Court.

"Balmoral Castle,

"Scotland, 25th Sept., 1896.

"Sirs,—Please forward to Balmoral Castle one dozen 2/6 Tins of BENGER'S FOOD for H.I.M. THE EMPRESS OF RUSSIA, addressed to Miss Coster. We have received the box ordered from Peterhoff.

"Yours truly, F. COSTER."

The Lancet describes it as "Mr. Benger's admirable preparation."

THE MEDICAL PRESS says:—"Few modern improvements in Pharmacy have done so much as Benger's Preparations to assist the Physician in his treatment of the sick."

The British Medical Journal says:—"Benger's Food has by its excellence established a reputation of its own."

The Illustrated Medical News says:—"Infants do remarkably well on it. There is certainly a great future before it."

A Government Medical Officer writes:—"I began using your Food when my son was only a fort-night old, and now (five months) he is as fine a boy as you could wish to see."

From an eminent Surgeon:—" After a lengthened experience of Foods, both at home and in India, I consider Benger's Food incomparably superior to any I have ever prescribed."

A Lady writes:—"Really I consider that, humanly speaking, Benger's Food entirely saved baby's life. I had tried four other well-known Foods, but he could digest nothing until we began the Benger.' He is now rosy and fattening rapidly."

BENGER'S FOOD is sold in Tins at 1/6, 2/6, and 5/-, by Chemists, &c., everywhere.

Wholesale of all Wholesale Houses and Shippers, or of the Manufacturers,

F. B. BENGER & CO., Ltd., Otter Works, Manchester.

S a preparation of the purified cholesterin fat of lambs' wool, nearly identical with the fat of the human skin and of the hair glands. It has been officially accepted for medicinal use be-

cause it readily penetrates the skin and is freely miscible with water and aqueous solutions of salts. For these reasons, and because it is the only trustworthy ointment basis for antiseptic purposes, it has been regarded as superior to all similar preparations. 'Lanoline' is supplied at 2s. 8d. per 1b.

Lanoline Preparations.

TOILET 'LANOLINE' is an effective skin emollient and protective which can also be advantageously applied to any mucous membrane. It is supplied in small and large collapsable tubes, at 4s. 6d and 9s. per dozen.

'LANOLINE' TOILET SOAP is carefully superfatted with 'Lanoline.' In cleansing the skin it renders it beautifully supple. It is supplied in boxes containing three tablets, at 4s. 6d. per dozen tablets.

London Cable and Telegraphic Address:-"BURC(ME, LONDON

A few Facts in favour of Scott's Emulsion.

Patients readily take and retain Scott's Emulsion when their stomachs and palates rebel against the plain cod-liver oil. A minute and uniform division of the oil is unquestionably an advantage, both in digestion and absorption. And in Scott's Emulsion this division is MAINTAINED INDEFINITELY, and the oil REMAINS FREE FROM RANCIDITY.

Glycerine is an important factor in Scott's Emulsion also, and should not be lost sight of. In the digestion of fat Nature makes glycerine; makes it for a purpose and uses it, thus showing the need of it. We add glycerine especially because it prevents fermentation, because it sweetens without aggravating uricacidæmia or glycosuria as sugar does, and because it assists absorption and aids nutrition. We owe much to the glycerine.

To the Hypophosphites of Lime and Soda we look for a necessary constituent of brain, nerve, and bone structure.

Is not the above combination better than plain cod-liver oil? And is it not a further advantage that the physician can absolutely rely upon Scott's Emulsion as being a PERMANENT EMULSION, FREE FROM RANCIDITY?

Original Communications.

TWO CASES OF METATARSALGIA.

By J. JACKSON CLARKE, M.B.LOND., F.R.C.S., Surgeon to Out-Patients at the North-West London and City Orthopsedic Hospitals.

METATARSALGIA was first described by Morton, of Philadelphia, in 1876, has of late been made familiar by various writers (a). The affection is rather a symptom than a substantive condition and results as a rule from the sinking of the heads of one or more of the metatarsal bones—i.e., a certain degree of transverse flat-foot. The sunken bone presses upon the superficial nerves and often a corn (b) forms over the head of the bone and increases the pressure upon the nerve. The degree of the resulting neuralgia and the determining cause of the condition vary. It may be a badly-fashioned boot first occasions the pain. Sometimes an injury closely precedes the onset of neuralgia. Rheumatoid arthritis in my experience appears to be a common predisposing cause. The two cases that I will now briefly narrate will serve to illustrate the fact that in equally severe cases sometimes the simplest measures suffice, sometimes only operative treatment serves to cure the condition.

CASE I.—A gentleman, æt. 34. General health good; no history of gout or rheumatism. He has attacks of severe pain which radiates from the head of the third metatarsal bone up the outer side of the leg to the thigh. The pain is more severe in some of the attacks than in others. It often persists when the boot has been removed. It prevents the patient from hunting as it is brought on by bearing the weight of the foot upon the stirrup. The pain has remained practically unchanged for six years, and it has greatly interfered with the patient's business. The condition dated from the patient getting his boots wet. After the boots had been dried the patient noticed a "rise" in them at the region of the ball of the toes. A corn developed at the seat of the pain; the latter is not relieved by removal of the corn. I found that the corn had formed over the head of the third metatarsal bone, and that pressure upon it started the pain.

This was one of the more severe type of cases, and I explained to the patient that an operation might be required, but before having recourse to it, milder measures should first be tried. I ordered a pair of stout walking boots, made upon Meyer's principle and furnished with rather thick soles, provided externally with a bar of leather three-eighths of an inch in depth and placed behind the heads of the metatarsal bones. After giving the boots a good trial the patient wrote to me to say: "I have had no discomfort since you had the piece put on the sole."

CASE II.—A gentleman, et. 35. General health good, but has had "rheumatism," father gouty. Two years ago when fishing in "waders" the patient felt some gravel inside the sock of the left foot and felt a pain which started inside the base of the little

(a) One of the most valuable recent contributions is that by Mr. Robert Jones, Liverpool "Medico-Chirurgical Journal," 1897.

(b) The patient often seeks advice for the treatment of this obstinate and painful corn.

toe (i.e. opposite the head of the fourth metatarsal bone) and radiated up the outer side of the leg and thigh. From that time the pain has continued to come on periodically, and in the leg it has latterly been constant. In bicycling the pain not only radiates up the leg and thigh, but is felt in the arm. After standing long the patient described the pain as excruciating, and it was often with extreme difficulty that he was able to perform his duties as a clergyman.

On examination I found the second, third, and fourth toes were slightly hyper-extended at the metatarso-phalangeal joints, and the pain was started by pressing behind the head of the fourth metatarsal bone. The same measures that were successful in Case I. gave no relief in this instance, so I decided to remove the head of the fourth metatarsal bone. This I did through a dorsal incision, removing part of the extensor tendons of the toe, the head of the bone, and dividing the flexor tendons of the toe in turn. Four weeks after the operation the patient's medical man wrote to me to say, "Mr. X's toe is easy, but there is no movement in it. The patient gets about very well." I last saw the patient five months after the operation. The fourth toe was straight, and both flexion and extension movements were normal. There had been no return of the pain after the operation, and the tenderness was completely removed.

In my experience these cases are equally common in hospital and in private practice. The operation of removing the head of a metatarsal bone is, of course, not a severe one. Care must, however, be taken to prepare the foot for a day or two before operation; and after cutting off the head of the bone the lower angle of the proximal end must be well rounded off.

HEY'S INTERNAL DERANGEMENT OF THE KNEE-JOINT. (a)

By JOHN KNOTT, M.D., Ch.B. (Univ. Dub.)

(Concluded from page 582.)

WITH regard to the other form of displacement, in which the semilunar cartilage alone is said to alter its position without the application of extreme violence, or the co-existence of extensive laceration of the other fibrous structures which enter into the formation of the joint, I look upon its occurrence in the normal anatomical state of the parts as a physical impossibility. Any anatomist who has taken the trouble to test the strength of the cornua which fix the cartilages to the head of the tibia, not to mention the accessory fastenings afforded by the coronary, jugal, and tertiary crucial bands, and the adhesions to the capsular (and internal lateral) ligament, will have, I think, but small faith in the evidence of a displacement engaging a semilunar cartilage only, and produced by a comparatively slight amount of external violence.

In many of these cases the history corresponds pretty closely to the following type:—A slight

⁽a) Read in the Surgical Section of the Boyal Academy of Medicine in Ireland, April 7th, 1899.

amount of violence is applied to the foot on its inner side, when the knee-joint is flexed: the ligaments and muscles about the knee-in the relaxed condition tion which corresponds to this posture are, as it were, thrown more or less completely off their guard. sudden acute pain is at once felt in the joint at the inner side, and the patient is unable to move the leg, which remains in a slightly flexed position, with a certain amount of abduction and external rotation. Sir Astley Cooper, whose description of the ætiology of this lesion corresponds more closely with my experience than that of any writer whom I have had an opportunity of consulting on the subject, has observed it to occur most frequently when a person in walking strikes his toe, the foot being at the same time everted, against any projecting body, such as the fold of a carpet. He also met with a case of the accident in a person who had suddenly turned in bed, when, the bed-clothes not allowing the foot to turn with the body, the condyles of the the thigh bone were believed to slip from the articular cavities formed by the semilunar fibrocartilages.

Very few autopsies have, so far as I have been able to ascertain, demonstrated the actual displacement of the semilunar fibro-cartilages of the knee-joint. specimen was described by Professor Thane in which the external cartilage was found displaced in a dis-secting-room specimen. Beid noted a case in which he had discovered (accidentally) in a dead body that the anterior segment of the external cartilage was detached from the tibia, and displaced backwards and inwards. This portion appeared flattened and widened, as if the displacement were of old standing. No history could, however, be obtained.

Verneuil has seen most of the cases of supposed luxation of the fibro-cartilages occur in rheumatic subjects, and would explain the symptoms present by the changes within the joint produced by this disease. He mentions a case in which he took the opportunity of carefully examining the movements of the joint in a highly emaciated patient whom he was treating for some other disease. In this individual, extreme flexion of the knee caused a prominence to form on the outer side corresponding in position and form to the outer margin of the external semilunar fibro-cartilage. Palpation gave, at the same time, a sensation of crepitation, and the patient felt some pain in the corresponding part of the joint. He observes, in conclusion:—"I believe that in my case no luxation of the fibro-cartilage took place, for the mobility of this cartilage is a normal condition. Accordingly, a new element must be added, which I believe to be syno-

It is observed by Panas (Dict. de Méd. et de Chir. Prat.) that all the cases of luxation of the semilunar cartilages belong to a period when the occurrence of loose cartilages in the interior of joints, and also the existence of arthritis deformans, had still remained unknown pathological facts, and he professes to believe that all the recorded examples of internal derangement of the knee-joint were but misunderstood cases of one or other of these conditions. this hypothesis he merely corroborates the views that had already been enunciated by Velpeau and by Malgaigne. The latter eminent authority also points out that in the cases in which (as in those recorded by Bassius and Dequevauviller) an abnormal projection was present, and supposed to correspond to the margin of the displaced cartilage, it was found on more careful inquiry that this projection had existed before the occurrence of the injury. In a case observed by himself, the projection had existed in a healthy limb, although to a somewhat less degree.

The fact that "internal derangement" may be confounded with a floating body within the joint was

surgeon detailed to the Académie de Médecine (apropos of an observation of luxation of the cartilages communicated by Londe) an account of a similar case which he had himself met with, and in which a corresponding diagnosis had been made. The supposed luxation recurred frequently, and the repeated trouble led at length to a more careful examination, disclosing the existence of a foreign body, which was afterwards extracted by Larrey

The most probable cases of luxation of the semilunar fibro-cartilages that have been recorded and perhaps, those of Lannelongue and Le Fort (communicated to the Societe de Chirurgie in 1879). The former was that of a girl, et. 11, who had previously enjoyed good health, and did not appear to auffer from any form of arthritic diathesis. Ten lunar fibro-cartilages that have been recorded are, months before entering hospital she had suddenly, while walking with her mother, and without any appreciable cause, experienced a sensation of crackling in the knee-joint. It was not accompanied by any sensation of pain, nor was progression at all impeded. The articular crepitus continued, and accompanied every movement of the joint. Two months later, walking became impeded; but it was not till eight months had elapsed after the original injury that pain was complained of, when it became so acute on any movement of the limb as to render walking nearly impossible. Examination of the joint when at rest gave merely negative results; nothing abnormal could be discovered by sight or touch; there was no displacement and no pain on pressure. When the extended limb was gradually flexed, a crackling sound was perceived as soon as the flexion had attained an angle of about 20 degrees; and, at the same time, a projection formed on the outer aspect of the joint which could be seen and felt.

When the limb was brought gradually back to the state of extension from the position of rightangled flexion, as soon as it had passed through an angle of 20 degrees in this direction, another bruit was heard louder than the first, with increased pro-minence of the tumour, after which complete extension (with subsidence of the swelling) followed without further opposition. The evidence of the hand and ear demonstrated that the bruit and the prominence corresponded to the interval between the outer condyle of the femur and the glenoid cavity of the tibia; while the displacement obvious to the eye on the outer side of the joint apparently impli-cated the external semilunar cartilage. This prominence formed a transverse ridge, occupying the line of the articulation in the depression on the outer side of the ligamentum patellæ; it was best marked in front. and gradually lost when traced backwards. When the finger was placed on the skin just before the formation of the swelling, it was found to be suddenly elevated with a peculiar vibratory sensa-tion, which conveyed the idea of an elastic band. It was compared by Lannelongue to the elevation of the skin produced by the pulsation of a large artery. After the formation of the swelling it remained till the second joint indicated the reduction of the displacement. On the inner side of the joint and normal. The reduction only was accompanied by that the only explanation of the phenomena which can be offered is that afforded by admitting the existence of a subluxation of the external semilunar fibro-cartilage. There was no evidence whatever of arthritis deformans; and he believes that the idea of a foreign body is out of the question, as the latter could not always persist in reproducing an identical deformity.

The case of Le Fort possesses a special interest, as it occurred in his own person. The original cause of the accident, as the sufferer himself observes, demonstrated in a case reported by Gimelle. This presents but few poetic details. This eminent sur-

geon happened to be in occupation of a position similar to that which the author of "Gulliver's Travels" leads his readers to infer was assumed by his hero after modestly retiring between two leaves of Brobdignagian sorrel. On this occasion the of Brobdignagian sorrel. On this occasion the professor, while resting on his feet, with both hip and knee-joints strongly flexed, suddenly experienced a distinct sensation of displacement in the outer part of the right knee-joint. When he raised himself from this posture the knee remained flexed, but a powerful effort restored it to the extended position. This effort was accompanied by acute pain, and a loud crackling sensation, as if some displaced object had suddenly returned to its place. All pain instantly disappeared, and freedom of movement was completely restored. The lesion subsequently reappeared on almost every occasion on which the knee was forcibly flexed, so that this movement had to be studiously avoided.

The above cases afford perhaps the strongest circumstantial evidence which I have been able to find of subluxation of a semilunar fibro-cartilage from

slight or indirect violence.

An interesting case of injury to the knee-joint was communicated to the Pathological Society of Dublin by the late Professor R. W. Smith (Feb. 4th, 1865), in which the fibro-cartilage appeared to have been displaced by a very unusual form of direct violence. It occurred in a boy of sixteen, who had been wounded in the knee by a hackle-pin, the sharp, curved point of which penetrated the joint on the inner side, and close to the line of the long saphena vein. The boy fell backwards, and the hook tore its way out. Escape of synovial fluid was followed by very severe inflammation, which yielded completely to treatment. On recovery, a certain amount of stiffness of the joint remained, the limb tended to remain somewhat flexed, and a distinct projection was found in the position of the wound, which presented a curved outline, was somewhat elastic to the feel, and, manifestly, was not of an osseous nature. The diagnosis in this case was that the hook which penetrated the joint had fixed itself in the internal semilunar fibrocartilage, and in tearing its way out had displaced this structure from its normal position. The possibility of a certain amount of displacement accompanied by laceration in such a case, cannot, I think, be questioned. The evidence afforded by the other cases quoted, as well indeed, that derived from the less important examples which we have found recorded by various surgical authorities, is not so conclusive.
Sir Astley Cooper observes that "under extreme

degrees of relaxation, or in cases where there has been increased secretion into the joint, the ligaments become so much lengthened as to allow the cartilage to glide upon the surface of the tibia, and particularly when pressure is made by the thigh bone upon the edge of the cartilage. The cartilages which receive the condyles of the os femoris are united to the tibia by ligaments, and when these ligaments become extremely relaxed and elongated, the cartilages are easily pushed from their situations by the condyles of the os femoris, which are then brought into contact with the head of the tibia; and when the limb is attempted to be extended the semilunar cartilages prevent it." There can be, I think, no reasonable ground for refusing assent to these views—as in the case of extreme relaxation of the ligaments, the existence of which was pre-supposed by this distinguished authority, the parts of the semilunar cartilages between their cornua must of necessity be very freely mobile, and comparatively easily displaced. But the case of a previously healthy joint is a widely different one; and, as I understand the phrase, "internal derangement of the knee-joint" deals with

the latter only.

Before summarising my conclusions as to the state

of things existing in the more typical forms of Hey's internal derangement of the knee-joint, I will relate the causes, symptoms, and treatment of the lesion as it has repeatedly occurred in my own person. It has always been the result of indirect, and, in every instance, very slight violence. The force has always been applied in such a direction as to produce rotation at the knee-joint—when already more or less flexed, and with the parts about the joint as relaxed as possible—when, indeed, if the expression be allowable, the muscles were almost or wholly off their guard. It has never occurred to me when the limb was in a decided state of active move-My first experience of the lesion occurred when a boy of about twelve, as I was slowly sauntering along a country pasture-field, I lightly struck the inner side of the point of my shoe against some elevation in the ground, and was instantly brought to a standstill by pain of an agonising character developed in the interior of the right knee-joint, and on the inner side. Besides the pain, I experienced the mingled sensations of fright and helplessness (as I was alone) to a degree which I have never forgotten. I soon reached the ground by what, I think, may be best described as a mixed movement of sitting and falling. The joint was slightly flexed, the leg slightly rotated outwards, and all will to attempt, and power to carry out, voluntary movement of the limb at the knee were absolutely lost. As this accident occurred many years before my initiation into the mysteries of anatomy, I need hardly say that I made no observations on the position of the bony prominences about the affected joint. But I very quickly applied my hands to either side of the knee, and instinctively made as strong pressure as I was able, with the vague hope of diminishing the pain. The continuance of the pressure had the effect of diminishing the flexion of the joint a little; when, suddenly, I felt an exacerbation of the pain, followed by a loud clucking sensation, which was conveyed both to hand and ear. This sound was followed by instantaneous and complete relief. No sequelæ followed. But the lesion frequently reappeared, from similar causes, and always yielded to the same treatment. It has also occurred when, in moving the right foot under a table, the inner side of the great toe has struck lightly against one of the legs. As at other times, this has occurred only when the knee was flexed, and the muscles which act upon that joint entirely relaxed. The total number of my personal experiences of this lesion would amount, I believe, to at least a couple of By exercising the greater caution which those painful experiences have taught me, I have for some years escaped its recurrence; but have from time to time been made to feel that the symptoms had narrowly escaped development

When I became a medical student, I naturally felt a good deal of curiosity about the slighter lesions of the knee-joint, but it was some time before I heard enough to send me to Hey's original paper. I there at once recognised a description of what I had myself experienced. The hearsay descriptions with which I had been previously acquainted had not given me the same impression. I embraced the first of my opportunities after this enlightenment to inform myself of the probable nature of the "internal de-rangement of the knee-joint," and have since been often able to make a hasty examination of the outlines of my own joint while still deranged. The evidence afforded by manipulation has added all its weight to the negative opinion which I soon formed from other considerations—that the semilunar cartilage has never in my case, nor in any correspond-ing case, been displaced from its tibial attachments. Two prominences could on such occasions, be detected on the inner aspect of the joint, one directly in-ternal, evidently formed by the inner border of the

internal condyle of the femur, and another, lower down and somewhat to the front, found on the inner side of the ligamentum patellæ, and presenting a better defined margin. This border, I have no doubt whatever, was formed by the superior margin of the semilunar fibro-cartilage, still attached to the upper end of the tibia.

Accordingly, my explanation of the nature of this lesion, which I look upon as a typical example of Hey's internal derangement of the knee-joint, is that by the combined slight rotation and external that by the combined slight rotation and external flexion—if I may be allowed to coin a new term—given to the leg, the tibia, with its adhering internal cartilage undergoes a process of subluxation. The articular end of the condyle being jerked over the upper edge of the latter structure, and there becoming hitched, the tibia has its upper extremity locked in a position of slight displacement forwards and outwards.

A similar rotation of the leg in the opposite direction, and an analogous displacement of the outer con-dyle constitute, I believe, the actual lesion in the comparatively rarer form of "derangement" which affects the outer section of the knee-joint. This relative infrequency is, to my mind, quite satisfactorily explained by the greater mobility of the external cartilage, and the existence of strong femoral attachments, which secure its adaptation to the varying resistions of the extense data. ing positions of the outer condyle.

Such I believe to be the only form of displacement which can occur in the previously normal knee-joint as the result of slight or indirect violence.

The lesions which occur in pathological conditions I have designedly excluded, as I do not think that

they should be examined under this head.

In concluding this rather lengthy communication I feel it to be my duty to apologise to my hearers for taxing their patience so heavily in a somewhat egotistical attempt to throw a critical light on an item of surgical mythology; and to reiterate with renewed emphasis the statement that an immediately reducible displacement of a fibro-cartilage of the normal knee-joint, such as most people seem to understand by "Hay's internal derangement," has never yet occurred.

Paris Clinical Lectures.

CONVULSIVE TWITCHING.

By Dr. GILLES DE LA TOURETTE.

[REPORTED BY OUR FRENCH CORRESPONDENT].

THE patient to whose condition I call your attention is twenty-two years of age. A few days ago she came to the hospital accompanied by her child and her sister, suffering, according to her statement, from St. Vitus's dance, which, from the spasmodic movements of the muscles of the face and of one half of the body, appeared at first sight, not improbable. Let me give you, however, the description which she herself gives of her condition: - Delicate in her childhood she was seized when she was eight years old with involuntary movements of the muscles of the face and soon afterwards her arms were similarly affected, so that she could only feed herself with some diffi-culty. Her parents brought her to the Trousseau' Hospital, where chorea was diagnosed, and she was submitted accordingly to the arsenical treatment. At the end of two months her condition had so much improved that she was able to return to school. Two years later the same symptoms reappeared but did not last long, and a year subsequently she was attacked for the third time. She was treated then by antipyrin, and with some success, but the affection

continued to return with more or less frequency, and according to her story, the present is her sixth attack. During these fourteen years the physicians whom she consulted, and they were many, all agreed as to the nature of the affection—chorea—and treated

her by arsenic and antipyrin.

Such is grosso modo, the clinical history related by the patient, and as you have observed, her remarks were accompanied by involuntary movements of the face and of the left side of the body. I must confess, however, with all respect due to the clinicians who pronounced the case to be one of chorea, whose prescriptions she showed me, my first impression was that the diagnosis required revision, and this for the

following reasons:-

In the summary statement made by the patient there was no question of nervous seizures; moreover, on close inspection of the muscular twitching one sees no rhythmical movement, we may consequently eliminate the affection known as hysterical chorea. Now, chorea, when it presents itself in a patient twenty-two years of age, is always of hysterical origin, the true chorea, that first described by Sydenham, never makes its appearance after the age of fourteen or fifteen. On the other hand, we must bear in mind that chronic chorea sometimes, though rarely, commences before that age, and the patient affirms that she had her first attack at eight years of

Such were the reflections which came into my mind, and my suspicions were confirmed by further infor-

mation supplied by the sister of the patient.

This woman declared that the twitching in the face had never totally disappeared since the age of eight, that her sister was in the habit, when worried by her child, of using bad language instead of making use of the ordinary expressions of vexation and reproof quite regardless of the presence of She had been frequently remonstrated strangers. with for using this bad language, but seemed to be unable to check herself. From that moment my mind was made up, and in lieu of the diagnosis of chorea, at once came to the enclusion that the case was one of convulsive twitching. It was in 1885, at the instigation of my regretted master, Professor Charcot, that I undertook the description of this affection. I sought to prove in my essay that the class of affections grouped under the name of chorea was far too comprehensive, and that it was necessary to withdraw from that group an affection not previously identified, which is in many respects similar to the chorea of Sydenham, with which indeed it had always been confounded. This affection begins in chilchood and develops in the same way as true chorea, at least in appearance, under the form of attacks of incoordinate movements of a certain duration, In contrast with what obtains in true chorea, patients suffering from the affection under consideration, are able to some extent to control and even, for a short time, to inhibit the twitchings of the muscles by an effort of the will. Further, once declared, this affection dogs the footsteps of the sufferer throughout life.

A year later, M. Guenon completed the description of the symptomatology. He remarked that the "twitchers" almostalways presented a certain degree of mental disturbance bordering on degeneration. Down to 1885 our knowledge of the malady was of the most summary, but during the lest few years it has been the subject of numerous investigations.

We will now inquire into the distinguishing features of this affection, which, as I have already mentioned, is so frequently confounded with the chores of Sydenham. Towards the age of seven or eight, a child, boy or girl—for the two sexes seem to be equally attacked—whose nervous heredity is almost always well marked, presents involuntary muscular

Digitized by Google

twitchings which sooner or later attract the attention of the parents. These twitchings are usually localised at first; they affect in preference the muscles of the face, twitching the eyelids, twisting the mouth with rapid and sudden movements of the lips. Sometimes these symptoms are accompanied by expiratory laryngeal sounds which later on assume a peculiar character. These phenomena may remain for a long time localised to the muscles of the face, but under the influence of causes difficult to define, the movements extend to the muscles of the shoulders and of the upper extremities. In the majority of cases the twitches do not present the systematic character of true chorea, and that fact is an important point in the differential diagnosis. Again, under the influence of the will, the convulsive movements can be arrested for a time, brief though it be, but they then recommence with greater intensity. I have alluded to an expiratory sound emitted by the larynx, a fact which shows that the muscles of that organ are also affected by the malady. This sound often consists of syllables like "hem," "oh," "ah," but as the patients advance in years words are pro-nounced, generally without meaning, but sometimes they are coarse and even licentious. A lady of Rouen brought me her son, æt. 10, to consult me for convulsive twitching, and told me that the boy had the habit of using words of the coarsest description in spite of all she could do to break him of the habit. so that she could no longer take him out for walks in frequented places. One of my colleagues related to me the case of a girl of 12, belonging to an excellent family in the south of France, who was constantly making use of a filthy expression. This, of course, very much upset her parents, who engaged a governess for the express purpose of breaking her of the habit, but it was of no use, the child continued to use the expression, and even seemed to take pleasure in so doing. Unless the word is of a filthy nature it would appear to have no value in respect of the diagnosis. It is true that the morbid stigmata does not show itself generally until the patient has arrived at the age of puberty, the case above mentioned being exceptional in this respect. The prognosis of convulsive twitching can never be favourable, as a complete cure is not to be hoped for; the intensity of the prognosis of the prognos sity and the frequency of the paroxysms can be reduced by appropriate treatment, but it is impossible permanently to arrest this morbid condition which has become, in a sense, inherent to the individual. Treatment should be exclusively of a moral order.

Clinical Records.

A CASE OF HÆMORRHAGIC INFILTRATION OF THE MYOCARDIUM WITH INTERSTITIAL MYOCARDITIS. (a)

Under the care of Dr. John'H. LARKIN.

THE patient was a man, æt. 87, who was admitted to Bellevue Hospital, January 16th, 1897, with the following history:-He had always been in good health till three weeks ago. He never had rheumatism; did not use beer Four weeks ago, on December 18th, 1896, he caught cold, but kept on working. For a week he was troubled with severe pain about the heart; the pain was not made worse by inspiration; it was of a lancing character, not constant. The pain still continued, but was not so severe as at first. On December 25th, three weeks ago, he had to stop work on account of shortness of breath and feeling sick generally. Dyspnœa, which was at first noticed a month ago, had gradually increased.

He had had orthopnea for three weeks. He had cough, with profuse expectoration. On January 14th he raised about one-half an ounce of blood. His feet were swollen. His temperature was 100 degs. F.; pulse, 116; respiration, 28. On examination the heart sounds were feeble and rapid. There was no murmur. The heart was enlarged; the impulse was in the axillary line, sixth interspace; the sounds were more distinct at this point. There were pleuritic râles over the cardiac region and the right base posteriorly. The pulse was small, weak, and rapid. When lying down there was pulsation of the vessels of the neck up to the lobe of the ear; when he stood erect, only half-way up, a harsh, short, diastolic murmur, most marked over the sternum, developed. On January 29th the patient was out of bed three times during the night. On the following morning, while sitting up in bed, he became unconscious, with twitchings of the entire half of the body, including the neck muscles but excluding the facial ones. There were yawning and lateral nystagmus, with diminution of the pupil of left eye. He had Cheyne-Stokes breathing. He died shortly afterward. At the autopsy nothing abnormal was noticed in the brain. The lungs were normal. The heart was slightly increased in size. There was no valvular lesion. In the wall of the left ventricle was a dark area, which contrasted sharply with the surrounding pale heart muscle, extending from the endocardial surface to about 3 mm. from the pericardial surface. The cardiac muscle in this area was dark and quite soft and depressed below surrounding muscle. A cross section showed the darkened area to be about 2 cm. long. The spleen was large and congested. The liver was in a state of chronic venous congestion. The kidneys showed a large congested surface; granular markings were not evident. Microscopical examination of the heart showed that the muscle in the infarcted area had been replaced by hæmorrhagic extravasation. Scattered through this blood-clot were remnants of dead heart-muscle cells, without nuclei, many containing larger and smaller vacuoles. At the periphery of the area was a narrow band of newly-formed fibrous tissue, with thin-walled blood-vessels and cedematous stroma. In places this tissue had proliferated between the muscle fibres so that it made a solid mass; and aside from the lesion proper it looked not unlike spindle-cell sarcoma. Changes in the coronary artery from the same case showed extensive obliterating endarteritis. There was showed extensive obliterating endarteritis. There was great thickening of intima, with secondary degeneration and calcification.

Transactions of Societies.

OBSTETRICAL SOCIETY. MEETING HELD WEDNESDAY, JUNE 7th, 1899.

MR. ALBAN DORAN, F.R.C.S., President, in the Chair.

SARCOMA OF UTERUS.

DR. W. S. A. GRIFFITH read brief notes of two cases of sarcoma of the uterus, both of which he had had under consideration for a considerable time. Case 1.-The patient, a woman æt. 52, was first seen in March, 1897. She had had several children the last nine years pre-There had been no menstrual irregularity until two years previously, but she then began to lose rather profusely, and this increased in amount. Twelve months before there was a flooding. A month before her seeing him she had a second flooding. Pain was never a prominent symptom. The hæmorrhage was always followed by relief of what she called pelvic discomfort. Quite recently she had complained of sharp pain in her womb, accompanied by a little offensive viscid mucous discharge. The cervix felt hard and irregular, but this was not borne out on actual inspection. He thought it a case of fibroid, and on March 13th he dilated the cervix, and found an interstitial fibroid of the posterior wall. She left well in May, but in September she still had irregular loss slight in amount, and had lost slightly

⁽a) Case brought before the New York Pathological Society, April, 1899.

in weight. He saw her again in July, 1898, when she looked well though losing weight. She had a clear blood-stained discharge. He did not see her again until this year when she had still further lost weight, the hæmorrhage being profuse and the uterus distinctly more bulky. He dilated and removed fragments of what proved to be sarcomatous tissue, and on March 23rd he performed hysterectomy. She recovered from the operation, but since then the right kidney had been removed for cyst, but this appeared to be independent of the original trouble, there being no sign of sarcoma in that organ. Case 2.—First seen December, 1897; single, et. 40. Menstruation had been regular since the age of 28. Had lost profusely for the preceding twelve months. For three months there had been much pain, but she appeared otherwise in good health. She became anæmic and emaciated, and the uterus reached three inches above the symphysis. A fibroid was diagnosed, and n June, 1898, he dilated and found a friable sessile mass on the posterior wall sections whereof pointed to a degenerating fibroid. She married agains advice six months later. When seen some time subsequently, the uterus reached 7½ inches above the brim, and there was a sloughing fibroid projecting through the vulva and a large mass was removed. The uterus then returned almost to its normal size, but it subsequently re-enlarged, and a polypoid mass was removed which proved to be sarcomatous. She died from septic trouble. The author insisted on the fact that profuse hemorrhages at the climacteric period were almost always attributable to organic mischief, and ought always to be carefully inquired into.

HYDRAMNION IN CASES OF UNIOVIAL OR HOMOLOGOUS TWINS,

Pr. Thomas Wilson, in a paper on this subject, pointed out that although twins derived from separate ova are seven times more common than those derived from a single ovum, hydramnion appears to occur nearly as frequently in the latter variety as in the former. His paper was founded on two cases of uniovial or homologous twins which occurred in the writer's practice, and on twenty other cases collected from various sources. The usual history of a case of this kind is that the patient usually a multipara, for the first few months of a pregnancy goes on normally. Then, usually at the fourth or fifth month and without any assignable cause, rapid elargement of the abdomen begins acutely, and leads in the course of a few days or weeks to extreme distress by reason of the severe pressure symptoms that are set up. The affection ends in nearly every case in premature delivery before the end of the seventh month; in the majority of the cases abour comes on spontaneously; in about 20 per cent. it has to be induced. The contents of the uterus are found to be twin fœtuses of the same sex, one of which is decidedly larger than the other and is enclosed in an amnion containing an enormous excess of fluid; the smaller feetus is provided, as a rule, with a normal or deficient quantity of liquor amnii. There are a single placenta common to the two feetuses, a single chorion, and two amnia. The heart and kidneys of the larger fœtus are hypertrophied, often, enormously. Neither feetus shows any malformation, and the mother is healthy the cause of the hydramnion is found in the relation of the vessels of the two feetuses to the common placenta. The twin whose vessels run a shorter or more direct course obtains an undue share of blood from the placenta, in which anastomoses take place between the vessels belonging to the two fectuses. In this way one fectus grows faster than the other, and its heart becomes not only absolutely but also relatively larger than that of the other; that is to say, its heart becomes really hypertrophied. This leads in some way to increased uptake of fluid in the placenta, and so to increased exudation by this twin This increased exudation takes the form of excessive secretion, certainly from the kidneys. probably from the skin, and possibly also from the portion of placenta belonging to the affected fœtus; and the accumulation of these discharges leads rapidly to enormous hydramnion of the same feetus. The diagnosis can often be completely made by observing that the signs of a feetus are limited to a small portion

of the circumference of a hydramniotic cyst. The approariate treatment consists in the induction of premature labour by puncture of the membranes. Case 1.—Seventh pregnancy; symptoms beginning at the fourth month; labour induced by puncture of the membranes at five and a half months. Larger feetus, contained in nineteen pints of amniotic fluid, with large heart and kidneys, thick umbilical cord with dilated vessels : smaller twin in separate amnion with normal amount of fluid, umbilical cord long, thin, velamentous; common placenta. Case 2.—Third pregnancy; symptoms beginning at three and a half months; labour spontaneous at five months; enormous gush of fluid followed by birth of twins contained in their membranes; larger twin hydramniotic; smaller showing marked atrophy of the wall of the left ventricle; common placenta and chorion. Dr. Wilson demonstrated the second specimen. The patient had been sent in as an urgent case, and while being put to bed there was a gush of fluid and the entire ovum was found in the bed. Both fœtuses were males, one being much larger than the other. In the larger twin the heart was markedly hypertrophied, the hyper-trophy specially involving the left ventricle. In the other feetus the left ventricle was thin (2 mm.) as compared with the 7 mm. of the left ventricle of the other feetus. The right ventricle of the smaller feetus was 4 mm. thick, being thus double the thickness of the left. The chorion and placenta were single. There were two cords. That attached to the larger fœtus was thicker, shorter, and attached to the centre of the placenta, while the other was attached to the margin. placents was roughly divided into two unequal portions, the larger section belonging to the larger feetus. Injections showed that there was a good sized vein running from one portion to the other.

Dr. Spencer insisted that the diagnosis was often extremely difficult, ballottement being often difficult to obtain. In one extreme case of his own he had obtained it only with the patient in the knee-elbow position. He suggested that before operating in such a case a sound should be passed into the uterus to ascertain its size. With regard to the alleged hypertrophy of the heart he pointed out that the organs of the fœtus varied greatly in size so that it was difficult to affirm that there was actual hypertrophy. He pointed out, moreover that the fœtus contained in the hydramniotic sac was not always the larger, and he had two observations in which the contrary was the case. The author's hypothesis would have to account for hydramnios when there was only one fœtus. In any event, the author's theory did not account for all the cases, and he urged that when there was an acardiac fœtus one would expect the other fœtus to be in a hydramniotic sac. In a well marked case of his own there was twisting of the cord, which he thought might explain some cases of hydramnios. The author's own experiments showed that the fluid might reach the sac via the maternal tissues and also via the fœtal tissues, so that on the whole the author's theory was rather hazardous.

Dr. Duncan said he had only seen two cases of hydramnios, but they were well marked. Both were cases of single pregnancy, and both were males. The last case had been diagnosed by three physicians as ovarian tumour. In this case, as indeed in both cases, it had taken several weeks to make the distinction, but in both instances it was possible to feel the feetus by placing the woman on her side and palpating both sides of the abdomen. Careful examination in both failed to make out uterine contraction, and that was a point of importance, because in text-books great stress was usually laid thereon. He presumed that the author would not suggest treating any of these cases in the absence of urgent symptoms. In both his cases labour supervened spontaneously at about the seventh month, and recovery in both was uneventful.

Dr. Griffith praised the author for having gone

Dr. GRIFFITH praised the author for having gone into the question of the source of the liquor amnii instead of taking it for granted. In reference to the urinary source of the liquor amnii, he pointed out the objection based on the difficulty of the feetus overcoming the pressure in the amniotic sac, even supposing that urine was secreted. As to the presence of varying quan-

tities of urea, he pointed out that there were no trustworthy means of ascertaining the composition of the small quantities of kidney secretion available.

Dr. A. ROUTH asked whether it was not a fact that many cases of acardiac monstrosities were described in which the hydramnios was in the sac of the acardiac feetus. The author's theory, moreover, did not explain hydramnios with a single feetus. He asked how it was that in these cases the feetus was generally puny, generally female, and why often malformed. He himself had been able to detect uterine contraction in two cases at the Charing Cross Hospital, and ballottement was easily obtainable.

Dr. SPENCER, in respect of the origin of the amniotic fluid from the fætal kidneys, added that in a number of cases of new-born infants he had found the ureters greatly distended when there had been obstruction below. If the fætus did not pass its urine into the liquor amnii it was difficult to explain this distension in the presence of obstruction. Without affirming that this was the source of the liquor amnii, the question was one that required to be answered.

Dr. GRIFFITH pointed out that similar distension had

been observed without any obstruction.

Dr. Spencer replied that he did not mean necessarily organic obstruction, which might be absent even in cases of hydronephrosis.

Dr. Griffith urged that the obstruction might be the

tension within the sac.

Dr. Spences rejoined that this would not explain all

Dr. Wilson, in reply, said that on the whole the evidence was in favour of the liquor amnii being at any rate in part derived from the kidneys of the fœtus. His paper only dealt with hydramnion in cases of uniovial or homologous twins, and he did not intend to discuss the subject as a whole. There were many varieties of hydramnios, of which this was only one group, and they required to be studied separately. With regard to the intermittent uterine contraction he said that he had failed to feel it in one instance, but the next day he had seen a wave of contraction.

ROYAL ACADEMY OF MEDICINE IN IRELAND-SECTION OF PATHOLOGY.

MEETING BELD FRIDAY, MAY 5TH, 1899.

The President, Dr. J. M. PURSER, in the Chair.

Dr. Knort exhibited a large series of pathological clavicles.

ANOTHER CASE OF INFECTIVE ENDOCARDITIS, DUE TO PNEUMOCOCCUS.

The Secretary (Professor E. J. McWeeney, M.D.), described a case of this disease. Into the left auricle projected a greyish friable mass of fibrinous material as big as a large hazel nut, and springing from the aortic cusp of the mitral. The chords tendines were involved in a mass of similar character, and were much softened and ulcerated. Microscopically and culturally the diplococus of Fraenkel was the only organism found. The edges of the fibrinous mass contained it in prodigious numbers, aggregated in small circular colonies. Both kidneys were found extensively infarcted, but not the spleen. Two months previously patient had developed a slight consolidation of both bases, consequent on a laparatomy successfully performed for the relief of pyloric obstruction by Mr. Chance. The temperature had been elevated at that time for two days only, and the case was regarded as one of so-called "ether pneumonia." She was discharged cured of her gastric troubles, and re-admitted a month afterwards with the symptoms of ulcerative endocarditis.

DISLOCATIONS OF THE METATARSUS ON THE TARSUS.

Professor Bennett read accounts of two cases of dislocation of the metatarsus on the tarsus, one of the complete dislocation of the bases of the metatarsals

upwards and outwards; the second an example of dislocation of the first, second, and third metatarsals downwards beneath the tarsus.

CENTRAL SARCOMA OF BONE.

Dr. E. J. McWeeney, commenting on a paper by Mr. W. J. De Courcy Wheeler on this subject, said that the two microscopical sections showed an enormous number of giant cells or myeloplaxes. The tissue resembled normal bone marrow, with an extreme multiplication of the myeloplaxes. The cells were of positively gigantic proportions, and some possessed about a hundred nuclei. The nuclei of many of the smaller round cells showed the mitotic figures, but there was no evidence of the mitosis in the nuclei of the myeloplaxes. As for the proposition of removing such tumours out of the sarcomata, he thought it impossible, for the simple reason that there was an unbroken chain of intermediate links between a round or spindle-celled sarcoma, with a very few giant cells, on the one hand, and a sarcoma crowded with such cells on the other hand. In Mr. Wheeler's specimen there was no tendency whatever to the formation of spicula of bone often characteristically formed in myeloid sarcomata.

myeloid sarcomata.

The President pointed out that in the marrow of normal bones the cells resembling the myeloplaxes were most commonly met with in young bones, and are very rare in the marrow of adult animals. He thought that the pathological myeloplaxes were something different from the normal giant cells of the marrow, which he

looked on as osteoclasts.

Mr. WHEELER, in reply, said there were no bony growths thrown out in the tumour. He raised the queswhether material like that occurring in the tumour shown by him was taken out of a similar case, could it be possible, seeing that there was so much spindle-celled element, to say positively that it was not a spindle-celled sarcoma, but a myeloid sarcoma.

TWO VASCULAR TUMOURS OF ABDOMINAL WALL.

Mr. R. Charles B. Maunsell showed two specimens which had been successfully removed by operation. The first was removed from the left lumbar region of a young lady, et. 22, and had been gradually growing from early childhood. It was large as an adult hand, and on examination proved to be formed of dilated lymphatic spaces, and of the same character as the congenital cystic hygromats of the neck. The second was removed from a baby, 11 months old, and proved to be a venous nevus. It had been noticed shortly after birth when it was not bigger than the head of a pin, and had rapidly grown until at operation it measured 16½ by 11½ cms., and covered fully a third of the baby's abdomen. It was ulcerated and constantly oozing blood. Mr. Maunsell removed it en masse, a very little blood being lost during the operation, the patient making an uninterrupted recovery, notwithstanding its tender age.

PATHOLOGICAL CONDITIONS OF THE TUNICA VAGINALIS TESTIS.

Mr. FAGAN, F.R.C.S., showed the following speci-

1. A large hydrocele opened longitudinally showing the relation of the tunica vaginalis to the testis, and demonstrating the several coverings of the tunica vaginalis, all of which were clearly shown by dissection. The external spermatic and transversalis fasciæ were thin, the cremasteric fascia thick and strong, and the tunica vaginalis thick. 2. A hydrocele associated with syphilitic disease of the testis. The tumour was removed for pain from a man aged 50 who had syphilis seventeen years previously. The testis felt stony hard, the tunica vaginalis moderately distended; pain was constant and unbearable. 3. A large hydrocele, due to malignant papillary neoplasm of the tunica vaginalis. Growth began first in summer 1898. Hydrocele was tapped twice; filled very rapidly after last tapping, and lost its translucency. Scrotum became purplish and covered with distended veins. No history of injury, syphilis, or gonorrhea; patient in 66th year and healthy, not even suffering pain from tumour. When tumour was opened a large quantity of yellowish black fluid poured out and the papillary growth became apparent. Castration was

performed April 12th, 1899. Patient left hospital

Professor McWerney pointed to the existence of a typical papillomatous carcinoma, originating from an endothelial membrane like the tunica vaginalis. The shape and appearance of the cells was almost identical with those composing a villous papilloma of the urinary bladder.

The President said that the specimen referred to by Dr. McWeeney was interesting, because the epithelium covering the sexual glands is, in the early stage, columnar in shape and several layers thick, and grows down to form the tubes of the ovary and the tubes of the testicle, so that the specimen might be a recurrence to the primitive type.

The Section then adjourned.

EDINBURGH MEDICO-CHIRURGICAL SOCIETY MEETING HELD JUNE 7TH, 1899.

Dr. Wm. CRAIG, Vice-President, in the Chair.

Mr. Shaw Maclaren showed a patient after disarticu-

Mr. C. W. CATHCART showed a patient after disarticulation at the hip for injury.

Mr. C. W. CATHCART showed a patient after operation for perforated vermiform appendix with general peritonitis.

Mr. F. M. CAIRD showed a case of secondary syphilis

occurring in a young man who presented undoubted signs of old congenital syphilis.

Dr. Sherman showed the following specimens:—(1) Malignant pustule; (2) sarcoma of the anterior part of the tempero-sphenoidal lobe, which had produced sudden the produced sudden the produced sudden to the produced hemiplegia; (3) calcareous deposit on the epididymis. probably of tuberculous origin; (4) extensive infarcts of the kidney; (5) a tuberculous nodule in the wall of the heart. This was a somewhat rare lesion; only eight cases were to be found in the pathological records of the Sick Children's Hospital for the last ten years. (6) Lungs showing diabetic phthisis.

Dr. James read a paper on a case of

CONGENITAL SYPHILITIC OSTEITIS.

The patient had been under observation for about, eleven years. A step-brother by a former marriage was healthy. By the second marriage there were eleven children, of whom patient was the third. The first and second was syphilitic, and died soon after birth; the fourth, fifth, sixth and seventh were premature, and either died soon after birth or were stillborn. The last four children were healthy. The patient had shown no signs of syphilis—such as shuffles or rash—at birth, but suffered from intestitial keratitis in his second year. When he was nine years old he began to suffer from pains in his arms and legs, and a node developed on the left tibia. Thereafter (in 1892) thickening of the lower ends of both humeri was detected, as well as nodes on the opposite tibia and on the spine of the scapula. Some years later he began to complain of headache, chiefly left-sided, and, simultaneously, twitchings of the right side of the body appeared, associated with transient attacks of unconsciousness. When admitted to hospital the lad was emaciated and apathetic. The right tibia was thickened and narrow, and about $\frac{\pi}{4}$ in. longer than the left. The vision was blurred, there were signs of old keratitis, and the optic discs showed fairly well marked papillitis. There was right hemiplegia with occasional clonic spasm. The vessels generally were thickened, and the glands and spleen enlarged. The diagnosis arrived at was hereditary syphilis with nodes which had disappeared and been followed by osteitis (local granlism of tibia), and a gumma in the rolandic area. At the post mortem the tibia was found to consist entirely of cancellous

tissue, the medullary canal being absent.

The discussion of the case, both by the speaker and by Drs. John Thomson, Alexis Thomson, and Sherman, centred round the question whether there was anything characteristically syphilitic ("para syphilitic") in such a case of osteitis, or whether (and to this view most of the speakers inclined) the osteitis was merely such as might

follow any chronic infection of bone.

THE GENERAL MEDICAL COUNCIL EDUCATION AND REGISTRATION.

SUMMER SESSION, 1899.

Sir WILLIAM TURNER, President, in the Chair.

FIFTH DAY-SATURDAY, JUNE 3RD.

AFTER the completion of a dental penal case, a report by the President to the Council on

PROPOSED INCREASED DISCIPLINARY POWERS

was read. It was to the effect that no great progress had been effected in inducing the dissenting licensing bodies to fall into line, and a resolution was agreed to by the Executive Committee approving of the amended clauses drafted by Mr. Muir Mackenzie and requesting the President to forward them to the medical authorities before submitting them to the Council.

Communications were received from the Privy Council enclosing copy of a proposed bill drafted by the Incorporated Association of Medical Practitioners for preventing persons who have been removed from the Register from continuing to act as medical practitioners.

Mr. Muir Mackenzie's opinion on the above draft bill was read. It was to the effect that if passed into law it would make it a criminal offence for such persons to continue to practice, which would be introducing an altogether new principle to existing legislation, a departure which would certainly excite strenuous opposition, and for this reason Mr. Mackenzie "could not advise the Council to support such a measure without very careful consideration. He called attention to the absence in the draft of any reference to midwifery, and he concluded by stating his opinion that the clause dealing with the payment to the Council of penalties inflicted under the Medical Acts was not framed in terms which would displace the contention of the metropolitan authorities. On the whole he did not think the bill was one which deserved the Council's support.

THE EXAMINATION OF THE APOTHECARIES' HALL, DUBLIN.

Then came up the reports from the Examination Committee on the inspection of these examinations. With respect to the examinations in October, 1898, attention is directed to the fact that the Board still manifested caprice in the allotment of marks, and appeared at times to adjudicate the work of candidates too highly. It is added, however, that the Board appears to have made considerable efforts to meet the suggestions of the Council. With regard to the examination in January, 1899, the Examination Committee note that they attracted as a rule men of inferior attainments "who were striving to pass into the profession by reiterated efforts in piecemeal fashion." The examination of April, 1899, consisted in the re-examination of two rejected candidates in a solitary subject of the second examination, and it is noted that these candidates were in process of securing a diploma by piecemeal examinations before different boards in 'different parts of the kingdom, a system "which could not be too strongly deprecated," and which has, moreover, already been condemned by the Council. With regard to the examination in surgery it is reported that the examination was well and fairly conducted.

SIXTH DAY .- MONDAY, JUNE 5TH.

The foregoing reports came up for discussion when Mr. TICHBORNE objected to the tone in which some matters of fact were stated in the reports, and he criticised the remarks of the two assistant examiners who 'rightly or wrongly" appeared to have acted as inspec-

Sir Dyce Duckworth pointed out that they acted as inspectors under the Act.

Mr. TICHBORNE moved the omission of the prefixes "one only" and "solitary" as superfluous, and he

Sir Dyce Duckworth pointed out that the use of the terms objected to was necessary to emphasise the fact that all this machinery had been brought into play for a single candidate. He added that the inspections had cost the Council £307 10s. 8d., which was a considerable amount in view of the paucity of the results.

Mr. VICTOR HORSLEY hoped the Council would support the committee, and commented on the expense which the inspections entailed. He suggested that the authorities of the Hall did not realise that they were carrying on the examinations at a loss.

Mr. TICHBORNE's amendments having been lost by large majorities, the motion that the reports be received and entered on the minutes was agreed to.

Sir Christopher Nixon raised the question whether the Council was to continue to incur the enormous expense of inspection, which he thought was out of all proportion to the results of the examinations.

The President pointed out that the matter referred to was not before the Council, though a motion to that

effect could be handed in.

Sir Christopher Nixon did not wish to take up a position which might appear offensive to the representative of the Hall.

THE STANDARD OF PRELIMINARY EXAMINATIONS.

Sir JOHN TUKE brought up the recommendations contained in the interim report for adoption. He explained the steps that had been taken to give effect to the Council's reference to the Committee, and stated that the replies received showed that the question was more complex than it at first appeared. While, on the other standard to the level of the senior local examination could be brought into force in 1905, the opinion was expressed on the other hand that, if not absolutely impracticable, it would not be practicable for many years to come. The Board of Delegates of Local Examinations of Oxford for instance, thought the proposal unwise unless it is intended to discourage candidates from beginning their medical studies until the age of eighteen. Notes of warning had reached them especially from Owens College and from Ireland. Another point raised was that the relative value of certain of the preliminary examinations accepted by the Council was not well defined. It was suggested that three men should be appointed, one for each division of the kingdom, who would take cognisance of the plans and regulations of the various bodies in order that they might see whether they are in accordance with the regulations of the Council. The experts and advisers might hold a conference with the Education Committee and draw up a report which he thought might enable the committee in November to suggest a course by which a system for gradually raising the junior examinations could be established.

The President then moved the adoption of the recommendations extending the period of reference and providing funds (£100) for obtaining expert assistance. This was carried.

REPORT OF THE MIDWIVES' BILL COMMITTEE.

Sir RICHARD THORNE read the report, which embodied a number of criticisms on the draft Bill. It is urged that the term "natural labour" should be retained, as otherwise women would be licensed to attend for gain cases of abnormality or disease connected with parturi-tion. It is suggested also that it should be made penal for a registered midwife to employ an unlicensed substitute, and prohibiting such registered midwife giving certificates of death or still-birth. It is urged that it ought to be made clear that the rules passed by the Central Midwives' Board should not be valid until approved by the Council, and the use of the term "qualifications" is deprecated as likely to lead to misapprehension. It is suggested that the local sanitary authority should take part in the local administration of any such Act, and attention is called to the "imperative necessity" of making provision for qualified medical assistance in all abnormal cases. Speaking on the Bill generally the committee advise that the term "license" should throughout be restricted to the permission granted by

the local supervising authority to practise in a given area and that the document granted by the Central Board should be termed a "certificate." Further suggestions are made in respect of the expenses which suggestions are made in respect of the expenses which Council or a committee might incur in connection with such bill. The committee accordingly recommend that the Privy Council be informed that the Council are unable to approve the Bill unless it is recast in accordance with the suggestions made in the report.

Sir Richard Thorne said there was one important

clause in the report in which he had been in the minority so that he could not propose the adoption of the report as it stood. After some discussion an amendment deleting the paragraphs concerning the sanction by the Council of the rules formulated by the Central Board was agreed to. The report was accordingly amended and in its altered form was directed to be forwarded to the Privy Council.

MEDICAL AID ASSOCIATIONS.

A report by the committee appointed to consider this subject was received. It embodies a narrative of the various steps that have been taken to investigate the practices complained of, and the committee suggest to the Council that, as the result of their protracted inquiry, "the evil is great enough to justify the expression of strong disapproval" by the Council of touting and advertising for the purpose of procuring patients in the medical aid department, and of any sanction to such methods by registered medical practitioners. A resolu-tion to this effect was suggested for adoption by the Council

In moving the adoption of the report Dr. GLOVER explained the action of the committee in respect of the proposed Board of Conciliation which he thought was the only practical course, and one which, it was to be hoped, would do much to remove the misunderstanding that had hitherto existed.

Mr. Horsley asked the Council to vote against the report, urging that they ought not to arrive at any conclusion without ampler information. He thought the report went too far, and he warned them against doing anything that might imperil the dignity of the Council or curtail its proper functions.

Mr. G. Brown, on the other hand, thought the recom-

mendation was worthy of a trial.

In reply to a question by Mr. Horsley, the President mentioned that in May, 1898, the Friendly Societies had a membership of 213,917, employing 75 medical officers, with an average of 2,849 members for each medical officer.

Mr. CARTER thought the proposal could do no harm,

and might do good.

Mr. BRYANT, Dr. LEECH, and Mr. TEALE supported the recommendation, but Sir RICHARD THORNE hoped that the representatives of the Council would take no part in the formation of any such Conciliation Board, if constituted. Though possibly very desirable he thought it would be a dangerous step for the Council to take.

Dr. MACALISTER approved of the recommendation, but Dr. McVail wanted to know more about the subject. He urged that its adoption might lead to disputes with persons who would probably have to come before the

Council to defend themselves.

After a long discussion on a rider to the resolution deprecating any participation by members of Council in the formation of such a Conciliation Board, a resolution was ultimately carried nem. con., declaring that the Council approved of the proposal to form a Conciliation Board consisting of representatives of Friendly Societies and medical men, on the understanding that the Council should not take part officially in the formation of the Board.

SEVENTH DAY-TUESDAY, JUNE 6TH. MEDICAL AID ASSOCIATIONS.

Resuming the discussion on Medical Aid Associations the PRESIDENT pointed out to Dr. GLOVER, chairman of the committee, that no means had been suggested whereby the Council could take action in the matter, and he asked him whether he would not supplement his motion by suggesting a course of action.

After some discussion, Dr. GLOVER proposed that a copy of the resolution of the Council passed on the previous day should be forwarded to the chairman of the committee, to the representatives of the friendly societies, and to the various professional bodies and members of the profession who had memorialised the Council on the subject.

This matter was ultimately postponed.
On the recommendation inviting the Council to declare that it "strongly disapproved of medical practitioners associating themselves with medical aid associations in which touting and advertising for the purpose of procuring patients is practised," Mr. Brown pose of procuring patients is practised," Mr. Brown asked Dr. Glover to substitute the terms of a motion standing in his own name to the effect that the Council "regarded as unprofessional" such conduct.

Dr. McVail pointed out that if they were prepared to take action against the persons referred to, then they should pass the motion, but he objected to the Council's

merely endorsing a pious opinion.

Dr. GLOVER, after some further discussion, said he wished the resolution to contain words sufficient to give notice that if persons lent themselves to such systems the Council would be prepared to use its disciplinary powers for the correction and removal of such persons. Ultimately the resolution was carried unanimously in the following terms: -" That the Council strongly disapprove of medical practitioners associating themselves with Medical Aid Associations, by which systematic canvassing and advertising for the purpose of procuring patients are practised.

THE ALLOCATION OF FINES UNDER THE MEDICAL ACTS. Dr. GLOVER brought up the report of the Penal Cases Committee on this subject, advising a test action. was discussed in camera.

ADDITIONAL QUALIFICATIONS ON THE COLONIAL LIST

The Council next proceed to discuss a communication from the Privy Council bearing on the claim of Miss Rachel Cohen, M.B., Calcutta, registered in the Colonial List, to have added thereto the F.R.C.S I. which had been refused by the Executive Committee on the ground that the applicant could not register her higher qualification on the Colonial List, the committee's action being based on an opinion by Mr. Muir Mackenzie.

Mr. Horsley moved that Miss Cohen's request be acceded to.

Mr. Muir Mackenzie admitted that his first opinion had been arrived at without a full knowledge of the facts, and ultimately it was decided to accede to the request and to direct the Registrar in future to register additional or higher qualifications on the Colonial List.

EIGHTH DAY .- WEDNESDAY, JUNE 7TH.

Mr. Carter made some caustic remarks on "the unbounded eloquence of certain members of the Council," two of whom, he said, had in five or six days made 133 speeches, thus unnecessarily prolonging the duration of the session. He ironically suggested that no member should speak more than three times on each motion.

The President announced that in camera the Council had decided to restore the name and qualification of

Mr. Alfred Freeman to the Register.

THE HUNTER CASE.

Mr. Horsley raised the question as to the presence of the Council's legal advisers on this occasion saying that it was not right for anyone to question the procedure of their legal advisers without it being arranged for them to be present.

The President said that both legal advisers preferred

not to be present.

After prolonged discussion, during which Mr. Horsley moved the adjournment of the debate in order to put himself in order, it was decided that the legal Assessor and Solicitor of the Council be asked to attend a meeting of the Council oh Thursday when the proceedings, re Mr. Hunter, would be discussed.

INSPECTION OF HIGHER EXAMINATIONS.

Mr. Horsley moved that the Council should record its opinion that under Sections xvIII. and xx. of the Medical Act, 1858, the duty is imposed on the Council of inquiry into, and securing, as far as possible, the efficiency of any examination which confers a registrable qualification mentioned in Schedule A of the said Act. He denied that Section 111. of the Medical Act, 1886, had any bearing on the point at issue.

The President asked Mr. Horsley whether he held that the Council would be entitled to refuse to put on the Register as an additional qualification a fellowship

conferred without any examination?

Mr. Horsley said this had no bearing on the point, though it was one well worthy of discussion. He was not aware that the Council, in expressing its recognition of any fellowship had ever laid it down that it was to be secured by examination.

Dr. MACALISTER thought that Section 20 of the 1858 Act limited the qualifications to those obtained after a

course of study and examination.

Mr. Carter pointed out that the examination out of which this question arose had ceased to be a registrable qualification since 1896.

The motion was put to the vote and declared to be lost, 9 voting against, 7 for, 12 did not vote, and 2 were absent.

THE APPOINTMENT OF THE LEGAL ADVISERS.

In response to the request of Mr. Horsley, the Registrar read the minutes of appointment by the Council of the Legal Assessor and Solicitor to the Council, and in spite of some opposition the answer was entered in the Minutes.

THE FIRST YEAR'S COURSE.

Sir John Batty Tuke moved that the report of the Education Committee on the regulations of the English and Scottish Conjoint Boards in regard to the first year's course of professional study be received and entered on the Minutes. The questions before the Committee were (1) whether a year of scientific study before registration should in exceptional cases be recognised as constituting one of the five years of the medical curriculum; (2) whether a year of scientific study taken after registration in an institution of the status and character of an ordinary secondary or grammar school should be regularly recognised as constituting one of the five years required. In regard to the first question the Committee state that experience has justified the protest against the practice, but it is pointed out that in all the Glasgow cases an examination had been passed which would have entitled to registration. With regard to the second question the Committee "regard the system with considerable distrust," and they report that the recognition of teaching institutions where physics, chemistry, and elementary biology are taught, without due inspec-tion, is not in accordance with Resolution II. agreed to by the Council in December, 1894. The Committee suggest that the Council should require that before registration is effected a student should have commenced medical study at an university or school of medicine or at a scientific institution recognised by one of the licensing bodies and approved by the Council. In this way attention would be drawn to any institution to which objection might be taken and approval withheld if thought desirable.

Dr. MACALISTER thought that registration should only take place in regard to institutions which had been formally brought before the Council and had been approved, in the sense that no objection had been raised.

Mr. Beyant said the report contained a principle which, as representing the College of Surgeons of England, he could not for a moment recognise. Most of the institutions had been recognised by the College only after inspection, and if the Council insisted that none should be recognised without inspection, it might be found possible to do so.

Dr. Church urged that the demands for registration ought not to be made too severe, and he moved as an amendment that the old form of registration certificate

be retained.

Sir WILLIAM THOMSON, quoting from the letter of the Secretary of the R.C.S.I., pointed out that according to the recently issued rules and regulations of the Conjoint Board in England it was possible to obtain a medical course of four years in spite of the Council's

requirements in favour of five years' course. He urged that it was the duty of the Council to see that their orders were carried out, and he commented on the attitude of a body which, when challenged, declared that it would act as it pleased. He insisted on the importance of the issues before them, and explained that with regard to the schools alluded to the contention was not that these schools were necessarily bad or inefficient for the teaching of science. He appealed to the Council to declare whether a first year at a grammar school was a bona fide year of medical study. He asserted that the Council had not intended that the additional year should be a sham, and if they approved of this departure from their rules the only alternative was that they must go back to the four years' system. It was idle to talk of a five years' course when it was not a five years' course. He asked the Council to accept the report, which was put forward as a recommendation and which, he hoped, would protect medical education.

Sir Christopher Nixon, speaking as the representative of the Royal University of Ireland, said that body had always rigidly carried out the Council's recommendations, and he asserted that, so far as the Dublin school of medicine was concerned, no school or secondary school professing to teach medical students the subjects of the first year's medical studies would ever be recognised. He expressed surprise at the attitude of the two great corporations, which plainly set the Council at defiance, and he urged that if this were allowed to pass it would possibly have a disastrous effect on other bodies that so far had tried to conform to the Council's directions. He claimed that the different corporations after inspecting these bodies should submit the results of such inspections to the Council for its approval. This appeared to him to be a test case with regard to the power of the Council, and if the Council felt it had not the power it might throw out the recommendations of the Education Committee. If they did so he feared they would undo all the good that had been done in years gone by in elevating the tone of medical education.

Mr. Brown cordially supported the committee's recommendations and urged the Council to adopt the fearless of consequences.

Dr. Macalistee pointed out that it was not alleged that the conjoint colleges had broken the rules laid down by the Council, indeed they had kept strictly to the letter of the law though they had interpreted the resolu-tions possibly in a sense not anticipated by the Council.

Dr. Atthill said there was a systematic process at work for whittling away at least one of the five years.

The PRESIDENT pointed out the corporations had actually submitted a list of institutions, but, as he understood it, they declined to limit their functions to a question of approval by the Council.

Sir W. T. GAIRDNER observed that science had been introduced into the programme of grammar schools to a much greater extent than ever before.

Dr. Church asked that his amendment might be put. He pointed out that it was not the desire of the Conjoint Board to run counter to the wishes of the Council, but objected only to the Council's going beyond what they held were its powers. It was not the business of the Council to regulate the curriculum of the Conjoint Board.

The amendment was put to the vote, and lost by 17 to 9.

Mr. Bryant complained that his college had not been properly treated, and he moved as an amendment that instead of the committee's recommendation the Council adopt a resolution in the following terms: "That the list of recognised teaching institutions forwarded to the Registrar at the beginning of each year be reported to the next following meeting of the Executive Committee and printed in the Minutes of that committee for the information of the Council."

The amendment was lost by 18 to 8, and the original motion was then carried. There were 18 for, 6 against,

5 did not vote.

The Registrar was directed to call the attention of the licensing bodies to the foregoing resolution.

NINTH DAY-THURSDAY, JUNE 8th.

An official notification was received from the University of Oxford appointing Dr. J. F. Payne its representative, vice Dr. Church, who had resigned. Dr. Payne was introduced by Sir Dyce Duckworth.

After a little spell in camera, a letter, with documents, from the Secretary of the College of Preceptors was entered upon the Minutes together with the President's

reply thereto.

REPORT OF PHARMACOPCEIA COMMITTEE.

The report of the Pharmacopæia Committee showed that 25,255 out of 26,500 copies had actually been sold, so that a re-issue was imminent. Note was taken of the fact that the Legislatures of Queensland and Victoria have sanctioned Acts which provide for the adoption of the British Pharmacoposia therein. It was announced that the Pharmaceutical Societies Great Britain and Ireland had been invited appoint representatives to confer with members of the Pharmacopeia Committee, and representatives had been appointed accordingly, and a conference had been held. The Committee suggest that they be authorised to allow the publication of reports received from experts in pharmacy and pharmaceutical chemistry upon matters deemed worthy of investigation. It was mentioned that the India Office and the Colonial Office had agreed to the request of the President of Council that a report upon the Indian and Colonial Addendum should be forwarded to the Indian and Colonial medical and pharmaceutical authorities. It was added that copies of the report had been sent to some 900 authorities and experts, and valuable observations and criticisms had been received in consequence. A committee has been formed in Canada to consider what additions it might be desirable to make in the addendum to adapt the Pharmacopæia to the requirements of the Dominion, and a preliminary report has already been agreed upon.

The report was adopted.

THE BRITISH PHARMACOPŒIA ACCOUNT.

On Mr. Beyant's motion it was decided not to charge the disbursements in connection with the preparation of the Pharmacopæia as part of the annual expenditure, but that a separate Pharmacopæia account should be kept.

THE FINANCES OF THE IRISH BRANCH COUNCIL.

It was agreed to refer the consideration of the financial condition of the Irish Branch Council to the finance committee with power to take legal opinion.

RECIPROCITY OF MEDICAL PRACTICE.

The Council then proceeded to taka cognisance of the opinion drawn up by Mr. Muir Mackenzie on the question whether the privileges to foreign practitioners could be restricted to the recognition of practice by them among their fellow countrymen only in this country.

Mr. Muir Mackenzie points out that Her Majesty may, by Order in Council, declare that Part 2 of the Medical Act (1886) applies to any foreign country. The effect of such order in Council would be to admit practitioners duly qualified in that country to registration here, and such registration would confer the right to practice medicine in the same way as English medical practitioners. Mr. Mackenzie, consequently, is of opinion that the privileges to foreign practitioners cannot be re-stricted in the manner indicated in the question.

The opinion as received was entered in the Minutes.

THE CASE OF THE LATE Mr. H. K. HUNTER.

After an ineffectual attempt on the part of Dr. McVail to postpone the discussion, Mr. Horsley asked and obtained leave to make a statement with reference to the proceedings taken in the name of the Council against the late Mr. H. K. Hunter, L.S.A. Alluding to the general impression outside that the Council had unustifiably undertaken proceedings against a duly registered practitioner, he repudiated on behalf of the Council any responsibility of the kind, seeing that the Council as a whole had never ordered that Mr. Hunter should be prosecuted for calling himself a physician, in fact, in ordering the prosecution, the Council was under the impression that the person to be prosecuted was an un-

registered practitioner using a bogus American degree. He complained that the Council as a whole had not been placed in possession of the facts of the case by the Penal Cases Committee.

Mr. George Brown reiterated the complaint that the Council had not been placed in possession of the facts of the case, and he believed that if the Council had known that the prosecution was against a registered practitioner, they would have hesitated before giving their sanction.

Dr. Glover defended the action of the Penal Cases Committee, and stated that the prosecution had not been taken in an unfriendly spirit, and was certainly entered upon without any personal animus. The object was simply to settle a question of law. He concurred in the regret which they must all have felt at the death of Mr. Hunter, but urged that the fact that he had died before the appeal came on was proof that the appeal was not resisted out of animus against Mr. Hunter.

Mr. Carter said the committee advised the prosecution simply as a legal test case on the right to make use of the Philadelphia degree. Mr. Hunter had expressed a desire to have the matter settled, and had intimated his willingness to defend any proceedings on the point. The imputation brought against the Council of having improperly resisted access to documents in this case had, he said, no foundation in fact.

The matter was then allowed to drop.

TENTH DAY.—FRIDAY, JUNE 9TH. RECIPROCITY OF MEDICAL PRACTICE.

The question of reciprocity of medical practice in regard to Italian medical practitioners, arising secondarily out of Mr. Mackenzie's opinion (see yesterday's proceedings), came up for discussion on a motion by Dr. McVail to the effect that the Executive Committee be instructed to communicate to the Privy Council the tenour of Mr. Mackenzie's opinion on the impossibility of limiting the practice of foreign practitioners to their fellow countrymen, the Committee to add a covering letter indicating the difficulties that surround the recognition of medical graduates in foreign countries over whose curriculum of study and professional examination the Council can exercise no supervision.

This was carried, whereupon Dr. GLOVER moved that a committee be appointed to consider necessary amend-

ments in the Medical Acts.

Dr. MacAlister and others opposed the resolution on the ground that the Council should leave the initiative in this matter to persons outside the Council. Ultimately the motion was rejected by a narrow majority.

APPOINTMENT OF EXAMINERS.

Mr. Stoneham was appointed assistant examiner to the Society of Apothecaries for five years vice Mr. Bernard Pitts.

It was also agreed to reappoint the present assistant examiners in surgery at the Apothecaries' Hall, Dublin, for one year.

THE ISSUE OF UNAUTHORISED DIPLOMAS.

The Council then proceeded to take into consideration the various memorials addressed to it in reference to the issue to persons not medically registered of certificates or diplomas testifying or implying proficiency in particular departments of medicine, surgery or midwifery.

Mr. Bryant brought up for adoption the recommendation of the Executive Committee absolving the Council from any present action in respect of certificates in midwifery in view of pending legislation, and stating that the Council, though it exercised no jurisdiction over spectacle-makers, would be prepared to consider any properly substantiated charge of improper conduct made against a registered practitioner with reference to the subject.

Mr. G. Brown moved an amendment to the effect that the matter be referred to a special committee to report to the Council in November next. He emphasised the importance, as matter of investigation, of the view that the assistance of medical men gave a quasi-medical character to diplomas conferred by outside bodies.

Mr. Horsley seconded the amendment, and insisted

upon the importance of the complaints embodied in the memorials.

Mr. Carter urged that the Spectacle Makers' Company was only endeavouring to assist spectacle makers in acquiring a knowledge of the mechanical part of their business. He thought that the Council would be going outside its province if it took any action in the matter.

The amendment was rejected by a large majority, and the original motion was then passed.

MIDWIVES COMMITTEE.

The Midwives Committee was reappointed, with instructions to watch any further legislative action that might be brought forward.

The Committee on Medical Aid Associations was also

reappointed.

DENTAL REPORT.

A report of the Executive Committee (Dental) was approved embodying the following supplementary notice:—
"Any registered medical practitioner who knowingly and wilfully assists a person who is not registered as a dentist in performing any operation in dental surgery, either by administering anæsthetics or otherwise, will be liable to be dealt with by the Council as having been guilty of infamous conduct in a professional respect."

On the motion of Sir J. BATTY TUKE, the senior examination of the Welsh Intermediate Board was added to the list of preliminary examinations qualifying

for entrance to medical study.

After the transaction of the usual formal business incidental to the fin dc session, the Council deliberately broke up.

France.

Paris, June 10th, 1899.

CACODYLATE OF SODA.

AT the Académie de Médecine M. Gautier spoke at length on the properties of cacodylate of soda, which he employed as a substitute for mineral arsenic in anæmia, intermittent fever, and in consumption, with considerable success. Cacodylic acid, he said, was rich in arsenical principles, since it contained 54 per cent. of metallic arsenic; but the arsenic is in this product in an essentially latent organic form, which deprived it of all the physical, chemical, and physiological properties of the ordinary arsenical preparations. It was evident indeed, that cacodylate of soda was not an ordinary arsenical composition, inasmuch as this salt reduces gradually but regularly the fever of phthisis, as he has observed in three cases, at the same time, stimulating assimilation, and rapidly increasing the weight of the body. Further, the stomach supported indefinitely from two to four grains daily, whereas they all knew that many patients could not take even the smallest dose of mineral arsenic. However, in cases of pulmonary consumption he thought that the best method of administration of cacodylate of soda consisted in hypodermic injections; the dose should be from half a grain to one grain in the twenty-four hours during eight days, after which there should be a rest of a week, and then continued for another week. The attendant would be guided by the state of the appetite and the temperature; if the former declined and the thermometer went up, the injections should be recommenced.

TUBERCULOSIS OF THE TESTICLE.

M. Delbet treated the subject of the treatment of tuberculosis of the testicle at the Société de Chirurgie. He considered from examinations he had made that the

Highmore bodies were frequently the seat of the disease and that these could be easily removed without touching the gland, which was much more rarely attacked. Consequently, castration should be proscribed in most cases.

FORMULA FOR VARICOSE ULCERS.

THE TONGUE IN INFLUENZA.

M. d'Hotel draws attention to a character of the tongue constituting a pathognomonic sign of that mysterious affection known as influenza. If the malady is observed during the first few hours of its invasion, the tongue may not present any abnormal feature, but the following day it is invariably covered with a white coating more or less thick towards the centre. Later on, according as the affection is of a benign type, or becomes complicated or prolonged, the lingual coating is seen to diminish from the point or on the contrary to remain. This label of influenza is in general the last sign to disappear, and it is not rare to observe three weeks after the début, a remainder of a whitish triangle at the base of the tongue, indicating that the patient not only has been through the malady, but also that he is not yet absolutely free from the morbid condition, although the general state of his functions may appear regular; an imprudence on his part, a cold, might provoke bronchopneumonia, gastro-enteritis or some other complication. Another characteristic of this lingual deposit is to redden litmus paper when rubbed on it, and not only during the first days of the malady, but as long as there remains a trace of it on the tongue.

This acidity persists as long as there remains any trace of the fur, and is a natural indication of the treatment which is that of frequently rinsing the mouth with an alkaline solution such as Vichy water, followed by the internal administration of the same. It is evident that influenza cannot be cured more than typhoid fever, but M. d'Hôtel affirms that complications were much rarer where the alkaline treatment was used.

Germany.

FROM OUR OWN CORRESPONDENT.

BERLIN, June 10th, 1899.

Hr. Heidenham, Worms, recited two cases at the Surgical Congress of

RENAL ABSCESS.

Hr. Kuster, Marburg, could not agree to any distinction between congenital and acquired renal cysts; in his experience all the cases were congenital. He would not decide as to Kronlein's case; but if acquired it was unique. In any case he would warn them against drawing a conclusion from it that nephrectomy was justifiable in cystic kidney. He considered the operation as forbidden under all circumstances. Some successful cures had been reported, but according to his conviction the cure was only apparent, and in all probability the patients died later on. In most of the cases that had been diagnosed as uni-

lateral careful examination showed that the other kidney was not sound, that the disease was progressing, so that removal of the first discovered tumour would be exceedingly dangerous to life. The question was, what was to be done in bad cases of cystic kidney? If on exposing a kidney a cyst was found, the other kidney should be exposed, and nephrectomy should only be performed after ascertaining that the other kidney was sound. The observation had been made that the worst symptoms had often been ameliorated, when the urine became suddenly loaded with foreign substances, a sign that the cyst had ruptured. Nature should be imitated, and the cyst opened, or if several were present, incision should be made in sections, and then sutured up.

Hr. Steiner, Berlin, treated a sixteen year old boy with a right-sided kidney cyst, whilst the left was healthy and not enlarged. A sister had died of bilateral kidney disease. He, like Kuster, was opposed to nephrectomy in cystic kidney, as the kidneys became diseased one after the other, and therefore if the second kidney was normal at the time disease would in all probability follow. Incision improved the general condition very much.

Hr. Muller, Hamburg, related the case of a man who had symptoms of renal calculns. Röntgen illumination revealed the presence of a stone, which on removal proved to be composed of carbonate of lime.

Hr. Samson-Hunelstjerna, Pless, had treated a woman who had suffered from cystic kidney for fifteen years. Large calculi were passed. After a time the pain on that side (the left) ceased, but then pain began on the right. An operation was performed. The kidney was not large, some calculi were seated on the calyx, not in the pelvis of the kidney. Three weeks later an ovarian cystoma was removed, upon which complete recovery took place.

Hr. Küster had a year ago performed double-sided nephrotomy for nephrolithiasis. The patient had suffered earlier from cystinuria; but not latterly, but instead of this pyuria from renal calculus. While in one kidney the calculus was a cystic stone, that in the other was a large phosphatic calculus.

Hr. V. Modlinski, Moscow, reported

Two Cases of Total Extinpation of the Bladder.

In one case death took place nine days after the operation. The second case recovered. He was of opinion that the operation was indicated:—1. When the walls of the bladder were thickly strewn with tumours. 2. In malignant tumours of the bladder, although the prognosis naturally was bad. The substitute for the bladder he manufactured from the vagina of the woman. With a man the rectum was cut across transversely 5 cm. above the sphincter, the ureters were let in to the lower end. The bowel thus cut across was closed up as to the upper end, and an artificial anus formed in the groin or loin.

Hr. Fritz Cahen, Köln, related the case of a woman who had

SWALLOWED A SET OF FALSE TEETH.

She was five months pregnant. She was only able to swallow a little water. On passing the sound, 15 ctm. from the mouth opening, it came on to a complete obstruction, The woman also suffered badly from struma, at the lower end of which was a hard resistance with a sharp-edged feel. Attempts to remove the obstruction made by a colleague had been without avail. The question arose whether the hard body felt in the struma

was the foreign body or only an ossification of the struma. Against the latter alternative was the fact that on swallowing the raw body moved upwards. But the struma also made a movement, and perhaps communicated it to the foreign body. Esophagotomy showed that the foreign body was not in the struma, but that the hard resistance was due to calcification. Unilateral strumectomy was then performed and the teeth found at the annular cartilage, they had caused a slight amount of perforation of the esophagus. A stomach tube was left in after removal and the wound closed by granulation.

Hr. Woermer recorded three cases of

UNUSUALLY LARGE OVARIAN TUMOURS.

1. On being tapped yielded 30 litres of thick viscid fluid. Later on perforation took place with subsequent peritonitis and death. Operation had been declined two years before death took place. 2. The weight not stated in this case. But the patient had for long been compelled to sit in a chair from the enormous size, and had suffered from great difficulty of breathing. Recovery after operation. 3. In this case the operation was successful. The tumours varied in weight between 60 and 112 lbs. In the last case the sudden removal of pressure led to hæmorrhage, diarrhæa, and bronchitis.

Hr. Levy-Dorn, Berlin, spoke on

RADIOGRAPHY.

He said that the technique had so far advanced that by a reinforcing screen images could be now taken on ordinary plates during one breathing interval. It was best to use the interval after inspiration for ordinary purposes. He showed two plates of the same individual, taken one in the inspiratory pause, and one in the expiratory one. He also showed a number of illustrations, echinococcus in the lungs with adhesion to the diaphragm, one-half of the diaphragm being raised up, a splenic tumour and bismuth capsules were found in the fundus of the stomach. The disturbing effects of respiration on these was well shown, as the man was photographed on both deep and shallow inspiration at the same exposure. In the picture, therefore, the capsules were seen lying one over the other.

Hr. Höllander, Berlin, spoke on his "Treatment of Lupus by Over-heated Air," and showed some cases.

Austria.

[FROM OUR OWN CORRESPONDENT.]

VIENNA, June 10th, 1889.

Paltaur showed a hardened preparation taken from the lung of a patient who had died of influenza. He thought that preparation demonstrated Kundrat's theory of lobular pneumonia as a result of influenza followed by purulent formation, necrosis, gangrene, induration, or subsequent purulent pleuritis. In his examination of the sputum of 100 cases, 56 on the post-mortem table and 44 who recovered, Pfeiffer's bacilli were found present both by Voye's test of agar cultures and animal experiments. These bacilli were found in spleen, kidneys, and meninges.

The preparation was from a young man, at. 30. The appearance was that of progressive purulent interstitial pneumonia, pneumonia dessicans, otherwise termed phlegmon or lymphangitis of the lung. One of the

lungs had multiple broncho-pneumonic centres with diphtheritic bronchitis in the large bronchi. The microscopic examination of the deposit on the surface revealed mixed streptococci among which were to be found the influenza bacilli.

MURPHY'S BUTTON.

Frank gave a record of his operation with the Murphy button, which was more favourable than Czerny's report of the apparatus. Among the cases submitted was one, a male, et. 57, whom he exhibited for inspection. This was a case of carcinoma of the sigmoid flexure where adhesions existed with the abdomen. In spite of the dangers that Czerny dreads, this case improved from the hour of operating without any gangrene or subsequent trouble. After eleven days the button came away, and the patient felt perfectly well. Frank thinks that apposition of the several parts is a principle that should not be forgotten. If the mucous membrane get in between the peritoneal surfaces union is imperfect; solid food should be longer delayed than after an operation by sutures.

Acute Lymphæmia.

At the Medical Club, Pineles showed a preparation taken from a patient, æt. 73, who came to him three months ago with giddiness, from which he recovered and felt fairly well till 14 days before his death, when the vertigo returned accompanied with weakness and general malaise. Four days before death there was hæmorrhage from the extremities and enlargement of the spleen, next day he became unconscious with tetanic convulsions, and died on the 19th day after the commencement of the second attack.

Examinations of the blood gave 3,000,000 red blood corpuscles and 500,000 white; of the latter 96 per cent. were mononuclear, or lymphocytic; the rest were polynuclear. There was no poikilocytosis or nucleated red blood corpuscles present.

From the post-mortem it was discovered that all the lymphatics were greatly enlarged, the kidney and liver were strewn over with white patches, the spleen greatly increased in size, while the marrow of the bones was very red, though the proximal ends had no fat on them whatever.

The strongest point of the diagnosis was the changes present in the medullary elements of the bones when examined by the microscope, as the lymph tissue was quite absent.

Pineles said that Frankel had endeavoured to distinguish leucæmia into acute and chronic, but this distinction he considers is too unscientific to be accepted.

On the other hand he thought some distinction should be made between leucæmia and myelæmia, the latter having nuclear red blood corpuscles, large fat cells, while little change in the elements of the blood are observed.

Pineles thought the specimen a good example of changes that take place in medulla of bone, at the same time demonstrating the alteration of function which is an important phenomenon in the animal economy.

The first of these changes is made manifest by the rapid disappearance of the polynuclear leucocytes from the blood, which proves the marrow to be an important centre of the hemopoitic changes. He considers acute

lymphæmia to be an infectious disease, and capable of being transmitted.

Elschigg confirmed similar hæmorrhagic effusions in the retina.

Pineles said that the fundus of the eye was perfectly healthy in his case, which is in accord with all the other cases recorded in the literature of acute leucemia.

Continental Bealth Resorts.

[FROM OUR SPECIAL CORRESPONDENT.]

MONT-DORE (PUY-DE-DOME, FRANCE).

THE season is approaching for the French summer resorts, and among these are prominently the Auvergne Springs of Central France. In the Puy-de Dôme Department alone are clustered within a limited and readily accessible district quite a host of renowned mineral-water establishments; notably those of Mont-Dore, La Bourboule, St. Nectaire, Royat, Châtel-Guyon, and Châteauneuf. Of these Mont-Dore claims the precedence, for its antiquity, celebrity of its springs, excellence of its establishment, superior altitude, and picturesqueness of its surroundings. Mont-Dore is over 3,400 feet above the sea-level, and the highest thermal station in Central France. The loftiest peaks in Auvergne (including the Pic de Sancy of about 6,200 feet altitude) arise around the small basin in which lie the town and fountains of Mont-Dore.

From the earliest days of the Gauls in France the Mont-Dore Springs have had their renown. And when the Roman rule succeeded that of the Gaulish chieftains Mont-Dore gained in celebrity. In these Gallo-Roman centuries Mont-Dore was at the acme of its prosperity. The statues, columns, votive tablets, vestiges of baths and other remains preserved in and about the present elegant establishment testify that there were not only most elaborate bath buildings but also a Pantheon, where the Romans and Gauls came to demand health from their different Deities, and to demonstrate by sculptured mementoes and laudatory inscriptions their gratitude to their gods for health restored. At Mont-Dore the very stones bear witness largely to the efficacy of its springs. This Pantheon and its adjacent baths were robbed and dismantled by the Vandal hordes of the fifth century, and the buildings finally destroyed during the raids by the Aquitaine kings in the seventh century-For many ages afterwards the historians do not mention Mont-Dore, and it is not until the fifteenth century that we hear much more about Mont-Dore. For a long time the lands on which are the springs had been attached to the feudal domain then known as "La Tour d'Auvergne." Guillaume de la Tour, Bishop of Rodez. in the year 1543, legally disputed their ownership with Antoinette de La Tour, wife of Jacques de Bourbon. The records, testamentary and of weddings, show the springs remained the property of the "La Tour" family until the eighteenth century.

We find the Mont-Dore Baths became again much frequented early in the thirteenth century. There is, however, little medically recorded about them until the writings of Jean Banc in 1605. In 1787 the value of the springs attracted the attention of Monsieur de Chazerat, the Intendant of the Province of Auvergne, who made a new road to them, and much improved the bath buildings. An entirely new and larger establishment was

erected during the years 1817-1823. Since then repeated enlargements and improvements have been made from time to time; until to-day Mont- Dore possesses one of the finest, artistically and scientifically, thermal establishments on the European Continent.

As to the waters themselves, there are thirteen mineral springs (only one of them cold), with an average total daily flow exceeding 200,000 gallons. The principal spring, "Madeleine," was only refound in the year 1823, when, in digging for some new foundations near the Pantheon, the ancient Roman aqueduct leading to this source was discovered. The water of the Madeleine Spring is of 113 degs. Fah, and used for drinking. It flows into a large handsome vase near the entrance to the hall set apart for ladies' foot-baths; yielding over 32,000 gallons every twenty-four hours, discharges itself noisily and with gaseous bubbles. Clear and uncoloured originally, after contact with the air it whitens as a sulphurous water, giving out an odour of carbonic acid.

The second in notoriety is the "Cesar Spring" (sometimes called also "Caroline") coming from Roman wells; bubbling loudly as it runs into the "Grand Salle" reservoirs: and setting free much caloric, which augments as the barometric pressure diminishes. It comes forth from the middle of a basin, cut out of a single stone, placed in a vaulted grotto of Gallo-Roman construction. The temperature is also 113 degs. Fah., and the yield nearly 27,000 gallons daily. The peculiar "buzzing" of this spring attracted attention in olden times; Sidonus Apollinarius commenting curiously thereon.

The waters from the springs, named "Saint Jean" and "Grand Bain" run steadily into the great lava bath of the Pavilion (where invalids are plunged) and various bathing-rooms. Their yield is over 12,000 gallons each twenty-hour hours, and their temperature (according to location of the different baths) varies from 104 degs. to 109 degs. Fah.

A comparatively new spring (found in 1891) called "The Singers" bubble out in the Pasteur gallery. It has a temperature of 116.6 degs. Fah., and yields daily between 33,000 and 34,000 gallons.

Taken as a whole the mineral waters of Mont-Dore are (at their origins) sparkling, clear, and without smell. They turn litmus paper red; have at first a slightly acid taste which soon becomes salty and astringent. To the touch they feel softer than oils or distilled water. Their main constituents are:—Carbonic acid, chloride of sodium, bicarbonate of soda, arseniate of soda, iron, and silica; with traces of lithium, manganese, borax, iodides, and phosphates. The vapours of the bath-rooms contain very much carbonic acid, a little iron and arsenic.

Besides the springs specially named above, are the Rigny, Ramon, Boyer, Pigeon, Chazerat, Boyer-Bertrand and "Pavillon"; from their constituents, temperatures and other leading characteristics, they apparently proceed from one great source; only varying because of the different strata through which they have respectively reached the surface.

The remaining "Sainte Marguerite" Fountain varies from 50 degs. to 55 degs. Fah. The country people call it *l'eau piquante*. It is not perfectly clear; evolves much gas; has an acid taste, changing rather to bitter, but is quite pleasant to drink with or without wines. It is used freely on the hotel tables; and is also employed to temper, when desirable, the baths given with the waters of the other springs.

The Operating Theatres.

KING'S COLLEGE HOSPITAL.

GASTROSTOMY FOR MALIGNANT DISEASE OF THE ŒSOPHA-GUS.-Mr. CARLESS operated on a man, æt. 56, who had experienced difficulty in swallowing for the last six months. The patient had been seen three weeks previously and urged to come in, but refused to do so. At the time of admission he was utterly unable to swallow, and was much thinner than when seen previously. Rectal alimentation was used for a few days and the patient's condition slightly improved. Chloroform having been administered the abdomen was opened through a linear incision extending down for 3 inches from the tip of the eighth costal cartilage, the fibres of the rectus muscle being separated. The stomach was found, and a conical portion pulled up into the wound the base of which was stitched all round to the parietal peritoneum. Mr. Carless said he had intended performing a Frank's operation, but the stomach was too small to admit of it, and therefore the apex of the cone was opened, a rubber drainage tube without lateral holes was introduced for about 2 cm, and stitched to the gastric wall, and the aperture in the stomach stitched to the skin at the upper horn of the incision. The fibres of the rectus muscle were freed from the posterior layer of the sheath, and drawn over the conical protrusion of the stomach and stitched together; the skin incision was then closed. Mr. Carless remarked that in several cases of gastrostomy for malignant disease of the cesophagus, he had found the stomach too small to permit of a Frank's operation being performed, and he had been utilising a variety of modifications. He thought it quite probable that the plan utilised in this case would prove as successful as any of the others, and it was certainly much simpler. In the typical Frank the apex of the cone was passed under a bridge of skin, and stitched to the margin of this second wound, with the idea of producing more or less of a valve. In cases that had lasted six months or more it was always found, however, that the passage into the stomach was direct and not angular. He thought that the sphincter-like action of the rectus in this particular case would prevent require itation. Another modification which he had utilised in a number of cases consisted in the immediate introduction of a rubber tube into the stomach; this remained fixed for about eight days, and prevented escape of gastric juice during that period, an occurrence not uncommon after the typical Frank.

As the patient was somewhat collapsed and in a bad state of nutrition an injection of food was made at once; though as a general rule Mr. Carless prefers not to feed the patient for twenty-four hours.

It is interesting to note that the patient has done very well; the tube was set free on the eighth day, and at the present time, two and a-half weeks after the operationthere has been no escape of gastric juice.

GUY'S HOSPITAL.

OPERATIONS FOR DISLOCATED SEMILUNAR CARTILAGE.

—Mr. Arbuthnot Lane operated on a man, who, during the last two years had suffered from sudden attacks of pain followed by considerable swelling of the knee-joint, which had incapicitated him on each occasion for about a fortnight. These symptoms were somewhat different

from those commonly seen in cases of damage to the internal semilunar cartilage, in that there was no pain, tenderness, or swelling along its attachment to the capsule, but that there was instead a painful tender fulness below and beneath the inner margin of the patella. On opening the joint in this situation the internal semilunar cartilage was seen to be doubled up in the interval between the two condyles, and to be attached solely by its anterior and posterior extremities to the tabia, having lost all connection whatever to the capsule. It was excised and the joint closed. Mr. Lane said that although he had operated on a very considerable number of displaced and damaged semilunar cartilages, he had never seen such a condition as that presented in this particular case.

The same surgeon operated upon another case of pain, effusion, and limitation of movement following damage to the knee-joint. The patient had made a sudden effort while supporting himself on one knee, when he experienced a sudden sickening pain in the part, and this was followed by a considerable amount of effusion into, and acute inflammation of, the knee-joint; this subsided slightly under rest, &c. The joint was tensely distended with fluid and very painful, a firm mass as big as the end of the thumb projected forward between the inner margin of the patella and the condyle of the femur. An incision was made over it into the knee-joint, where this lump escaped suddenly through the opening made; it resembled, in appearance, a lump of gangrenous omentum, and on section appeared to be a portion of the ligamentum mucosum which was distended with extravasated blood and very acutely inflamed. The contents of the joint appeared almost purulent in character. The mass was removed, the joint cleared of its fluid and lymph and the wound closed Mr. Lane said this case presented conditions that in his experience were very unusual. He believed that the synovial fringe had been violently compressed between the ground and the under surface of the internal condyle. In a paper published in the British Medical Journal, December 2nd, 1898, entitled "Detached Pieces of Articular Cartilage forming Loose Bodies in both Knee-joints," he pointed out that if a person kneels on one knee an area of the under surface of the internal condyle is exposed to direct pressure. In the present case it would seem likely that a portion of the ligamentum mucosum was included beneath the condyle as already remarked.

Vital Statistics.

The deaths registered last week in the thirty-six great towns of the United Kingdom corresponded to an annual rate of 16.5 per 1,000 of their aggregate population, which is estimated at 11,404,408 persons in the middle of this year. The deaths registered in each of the last four weeks in the several towns, alphabetically arranged, corresponded to the following annual rates per 1,000:—

Birkenhead 15, Birmingham 16, Blackburn 19, Bolton 17, Bradford 16, Brighton 8, Bristol 14, Burnley 21, Cardiff 11, Croydon 13, Derby 15, Dublin 22, Edinburgh 20, Glasgow 20, Gateshead 17, Halifax 17, Huddersfield 16, Hull 17, Leeds 17, Leicester 15, Liverpool 24, London 17, Manchester 26, Newcastle-on-Tyne 17, Norwich 13, Nottingham 15, Oldham 22, Plymouth 19, Portsmouth 17, Preston 22, Salford 20, Sheffield 18, Sunderland 17, Swansea 18, West Ham 10, Wolverhampton 22.

"SALUS POPULI SUPREMA LEX."

WEDNESDAY, JUNE 14, 1899.

THE GENERAL MEDICAL COUNCIL.

THE, we believe, absolutely unprecedented length to which the but recently concluded session of the Council has run to, is the natural outcome of the more enlightened policy which has of late years actuated that body. It has now, to some extent, awakened from the lethargy which characterised its earlier existence, under pressure of public opinion. and year by year the number of important questions interesting the profession at large, tends to increase. The prospect is opening up of the necessity for multiplying the meetings the better to enable it to cope with the additional work which recent events have thrown upon the Council. When we learn from the caustic tongue of Mr. Carter that two members made a hundred and thirty-three speeches in five days between them, we need no further proof of the earnestness with which some, at any rate, of the members of Council approach the matters before the Council.

A glance through the summarised report of the proceedings which we publish elsewhere will convince our readers that the Council has done some good solid work during this protracted session. There has been singularly little waste of time on personalities or in vain discussions of a technical order. On the other hand, several highly contentious and exceedingly important questions have been adjudicated upon. The question of the standard of preliminary education has been advanced a stage in that a definite plan of investigation has at last been decided upon. If the committee are to be believed, the issues are far more complicated than was thought, and we find that the proposal to raise the standard to that of the senior local examinations is declared by one authority

to be impracticable, "unless it is the intention of the Council to discourage students from commencing their medical studies before the age of eighteen.' That, indeed, were a consummation devoutly to be wished, and it of itself constitutes a very cogent argument in favour of the change. We are promised a working report for next session, and we hope we shall get it.

At last the Council has taken a definite stand in respect of the association of registered medical practitioners with institutions of the medical aid type which systematically advertise and tout for patients. Such medical officers are warned in no uncertain terms that such associationship will be regarded by the Council as calling for the application of the penal powers vested in the Council, but the cutting edge of the resolution has been taken off, or at any rate blunted, by a resolution approving in abstract of the formation of a Board of Conciliation, in the organisation whereof the Council will studiously abstain from taking any official part, but which, it is hoped, will help to get rid of the misunderstandings which at present exist. We have every confidence that this resolution will of itself go far to remedy a condition of things which amounted to a scandal. Unscrupulous practitioners will no longer be able to take refuge behind a board of management, but will be held responsible for the sanction which their association with the peccant societies implies.

We are pleased to announce that the Council has broken away from the hidebound interpretation of the Medical Act which led the Executive Committee to refuse to add the fellowship of the Royal College of Surgeons in Ireland to the name of a lady who was already registered in the Colonial List in virtue of the M.B. of Calcutta. The Council's legal adviser virtually withdrew his opinion after some arguments by Mr. Horsley, and in future the Registrar has been directed to admit such additional or higher qualifications to the Colonial List as a matter of routine. We must, however, express our regret that an ill-advised legal opinion on this point should have placed the Council in such a false and undignified position.

The question of the inspection of the so-called higher examinations, raised by Mr. Horsley, is more complicated than it at first sight appears. They are unquestionably qualifying examinations and as such they ought to be inspected by the Council. If the terms of the law were strictly adhered to such additional qualifications could only be granted after a specified course of study but, as is well known, the fellowships are not unfrequently conferred on persons of professional distinction without any examination at all, and it would be difficult to defend the admission of these diplomas, conferred honoris causa, to the Register. Although Mr. Horsley made out a very clear case for the interference of the Council this body resolutely declined to be drawn into a departure from established custom, though in all probability we have not heard the last of the contention.

MEDICAL MEN ON HOSPITAL COMMITTEES.

As many of our readers are aware, a dispute has lately arisen among the governors of the London Royal Orthopædic Hospital as to the administration of the affairs and the general policy of that institution. It appears that for many years complaint has been made of the serious insanitary state of the building, indeed, more than two years ago Professor Corfield made an order for re-construction of drains, which was stayed only on the understanding that the hospital was to be rebuilt or removed. The old committee proposed to sell the site of the hospital for £28,000, but a recent independent estimate from an expert has placed the value at £36,000. In view of decreasing income and increasing expenditure, and of the failure of the old committee to take any effective steps to set matters straight a number of governors elected eight new members of committee, and re-elected five of the former members. After some protest the old committee called a general meeting to discuss the charges that had been brought against them. A perusal of the report of that meeting goes far to condemn the position taken by the old board of management. The complaints against their administration were brought forward in a perfectly clear, reasonable, and moderate way. As shown by the published reports they were met by speakers on the other side chiefly by attacks on the good faith and intentions of those who had advanced the criticisms. What was the main point? the insanitary condition of the hospital was ostensibly the rock of offence. That defect was substantiated by the testimony of the medical staff, by the action of the Medical Officer of Health for the district, by the commissoners of the Prince of Wales's Fund, and by the records of the hospital for many years past. We submit, then, that the old committee must have poor grounds of defence in the face of so sustained a proposition if at a public meeting their speakers descend to the level of Billingsgate debate and call their critics "raiders," and assert that almost every sentence of pointed criticism is absolutely false. But that which most nearly affects the medical profession is the law carried by members of the old committee to the effect that "no acting medical officer of the hospital shall be eligible for election as a member of the committee of management." This motion was introduced by the deputy chairman of the old committee in language that fortunately is not often heard He advised the governors in public meetings. to " clear out the whole of the present medical staff," especially Mr. Reeves, whom he designated as an "arch-conspirator" in the "raid." Here, again, we fail in the heated language to trace the dignity of men of standing whose judgment in administering a charitable undertaking has been assailed. Such views will naturally suggest that committeemen must have some serious reason

honourable profession at their deliberations. As a member pointed out, the tone of the vice-chairman's speech was better fitted for a meeting of angry city speculators than for a benevolent society. The members of the old committee, although outvoted by two to one at the meeting, yet carried their point by proxy, a most unsatisfactory way of wining a victory. Then they resigned in a body, which, again, points to animus, because if they intended to secede they could perfectly well have left it to their successors to decide whether they wanted any of the honorary staff on the management. Then, again_ why should they retire without courting full investigation of the constitution and proceedings of the old committee with regard to the proposed sale of the site? To those who are behind the scenes of the professional philanthropic stage, the violence of the defence will suggest the desirability of a thorough investigation of the facts of the administration of the Royal Orthopædic Hospital during the past few years. It is hardly necessary to remark that of late the view has gained ground among the medical profession that they should be represented fully on every hospital management, both in the person of members of the honorary staff and also of outside practitioners. If that plan were more generally adopted it is likely that less would be heard of the need of reform of hospitals. What can the public think of a committee that when approached in a spirit of impartial criticism replies by vollies of abuse and a recommendation to exclude from any voice in the affairs of the institution the members of the profession whose gratuitous services render the existence of the charity possible? So far as the Royal Orthopædic Hospital is concerned, we can only say that the full details of the attitude of the old committee with regard to the insanitary state of the hospital and to the proposed sale of the site will be required before general con. fidence can be restored to its former basis. Perhaps some energetic public journal will sift the matter and give a clear account of the facts of the case. Things have now gone so far that such a course should be welcomed by all real friends of the hospital, which can suffer nothing but injury by any attempt at concealment.

THE "GRAMMAR SCHOOL" SCIENCE YEAR.

pital shall be eligible for election as a member of the committee of management." This motion was introduced by the deputy chairman of the old committee in language that fortunately is not often heard in public meetings. He advised the governors to "clear out the whole of the present medical staff," especially Mr. Reeves, whom he designated as an "arch-conspirator" in the "raid." Here, again, we fail in the heated language to trace the dignity of men of standing whose judgment in administering a charitable undertaking has been assailed. Such views will naturally suggest that committeemen must have some serious reason for objecting to] the presence of members of an

hour the prescribed five years of work, London colleges, however, having once entered upon the wide and smooth road of gathering into their fold all schoolboys-diplomates in posse, thought they might venture to throw aside the obstruction which prevented their giving such boys a full year's credit to begin with, and, with careful noiselessness they advertised that their bread and butter proteges could enjoy that benefit. When this move was spied by the Irish College of Surgeons it, forthwith, took the whip in hand, with which it and its Irish and Scotch colleagues have administered a wholesome and much-needed castigation to the London colleges. On the matter being brought to notice the Education Committee at once took it into consideration and, the facts being indisputable, reported more than once that the action of the London colleges was intolerable, and must cease at once. When the report was being brought up at the meeting of the Council the opening of the case on behalf of the complainants devolved, practically, on Sir William Thomson and Sir Christopher Nixon, who were ably supported by Dr. Atthill, Sir William Gairdner, and Dr. Bruce. Sir William Thomson maintained that the Conjoint Board for England was pursuing a course of action which was offering a four years' course instead of the five years' curriculum recommended by the Council. He maintained further that this action was in absolute opposition to the Council's requirements and recommendations, and yet from their statements the representatives of the Royal Colleges of England apparently intended to stand by the position which they had assumed. He (Sir William Thomson) wanted to know what the Council now proposed to do. He had been of opinion that the Council had direction of these things, and it was for them to see that they were carried out. But according to what they had heard to-day all those considerations were to be put aside by the two Royal Colleges of England, who seemed to say that independently of anything that the Council proposed they would do what they liked. If the General Medical Council was impotent in regard to its own rules, there was no use in coming here at all. He was perfectly sure that the Council had no intention of making study in science at a grammar school equivalent to a first year's medical course. There was no question that what the Council intended was that the first year's medical study should be study at a university, medical school, or "scientific institution approved by the Council." That was exactly what they wanted to-day. He could not understand how they were met at the threshold by two powerful corporations saying that they would not obey the General Medical Council. The net result of the debate, after a practical admission of the facts by Mr. Bryant, was that, to exclude the possibility of recognition of a grammar school, the limitation to a "scientific" institution "approved by the Council," was carried by a majority of eighteen votes to six. We trust that the London colleges will lay to heart this severe lesson that the regulations of the General Medical Council cannot be abrogated for their advantage.

Aotes on Current Topics.

The General Medical Council and the Apothecaries Hall, Ireland.

THE Examination Committee of the Council, under the guidance of Sir Dyce Duckworth, has had a fine day's sport at the ignoble pastime of baiting the Irish Apothecaries Hall, a proceeding in which all the discredit lies with the persecutors and all the sympathy with the persecuted institution. The Council, having been defeated hefore the Privy Council, set itself with immense gusto to tie up the Hall with all sorts of examinational bonds, the effect of which must be to weigh down the institution with expenses, and to cause its examinations, if carried on at all, to be carried on at a heavy loss. It was called upon to appoint two delegate examiners and one inspector and no one can complain if these officers were liberally paid. The "Hall" acted with great discretion, determining to give its detractors no fair opening for attack, and to spare neither trouble nor money for this object. Three series of examinations were held in October, 1898, January, and April, 1899, and the reports of examiners and inspectors lie before us to the effect that the examinations were all "sufficient." and were conducted with great care. There is no more of adverse criticism to be found in the reports than in the reports on other licensing bodies. and, on the whole, it may be taken that, as regards the thoroughness of its examinations the "Hall" came off sans reproche. number of candidates, however, was extremely small, not more than one or two, sometimes none, for a division of the examination, and some of these were men who had been rejected in one or more subjects before and were now again repulsed. To us it is remarkable that any candidate offered himself, considering the energy and ingenuity which this Examination Committee has for years devoted to crying "mad dog" against the "Hall." but none the less does Sir Dyce Duckworth and his colleagues seize the paucity of candidates as the occasion for assault. His reports to the Council are punctuated throughout with sneers at the institution which, as we have said, reflect upon his Committee rather than upon the "Hall." It appears that the assistant examiners and inspectors have cost the Council £307 within fifteen months, a circumstance which, we suppose, does not disturb the equanimity of the "Hall." It is not any part of our policy to sustain the existence of the "Hall" as an independent qualifying body, and we have said a thousand times in years past that we anxiously desire to see it absorbed out of existence, if possible, by making it the third, or pharmaceutic side of the Irish conjoint qualifying triangle. The oppressive dignity of the Irish College of Physicians has prevented this solution of the trouble, and the General Medical Council, instead of putting strong pressure on that body to assent, has elected itself to the function of supporting its policy by squelching the "Hall" per fas aut nefas. We regard such tactics

in our power.

The Birthday Honours and the Anti-Vivisectionists.

A CHARACTERISTIC letter was published last week in the Standard from the Hon. Stephen Coleridge, protesting against the honours conferred upon Professors Burdon Sanderson and Michael Foster, because of their supposed vivisection practices. It is really difficult to understand how such a letter ever was published, but as it has been, it should not be allowed to pass without comment. San derson is represented as having slowly smothered dogs alive (sic)—smothering dead dogs is a process which has not come within our experienceand chronicled their dying convulsions. Then a quotation is given from the "Handbook for the Physiological Laboratory," descriptive of experiments in connection with asphyxiated animals, concerning which Mr. Coleridge points out that no mention is made of the use of anæsthetics. The unfairness of the attack is that this champion of antivivisection entirely omits to state that the experiments referred to were performed long before the Antivivisection Act was ever heard of; whereas the intention of the accuser obviously is to give the public the impression that the experiments were only recently performed. That is to say that in the opinion of Mr. Stephen Coleridge, a distinguished scientist who performed some experiments, presumably without anæsthetics, upon animals a quarter of a century ago, should never have been rewarded by the Queen for his great scientific ser-Verily the narrow-mindedness of these "Anti" faddists constitutes a serious disease. The absurdity of the position which they assume makes it impossible for ordinary mortals to act charitably towards them in such matters and excuse them upon the grounds of eccentricity. It was a wonderful answer which a celebrated divine once gave to a noted agnostic. "I am an agnostic," declared the latter-"So I understand," was the reply, "but I suppose that you would not be flattered were you to be described by its equivalent—namely, an ignoramus"-so it is with many of the "Anti" community; they make everything tally with their misguided ideas, and are apt hands at perverting the truth.

Fashion in Faces.

One result of the forward movement in womenkind is the appearance of a luxuriant crop of cherry cheeks among the fair sex of the middle and upper class. It is no longer the fashion to be lily-white and pale as of yore, but rather to court the ruddy look of the milkmaid. This change confronts one in the parks, in the public streets, in the drawing-room. in the theatre, in church, everywhere, in short, where the dominant sex congregate. To a great extent it is no doubt due to the passion for open-air exercises that now reigns almost as supremely as among the boisterous athletic male. A short genera-

as utterly unfair, and will lend them every opposition tion since, when fair woman deserted her mild domestic occupations and accomplishments for "carriage" exercise or horse-riding she had wellnigh exhausted her round of out-door recreations; whereas now, at the close of the Victorian era, she has golf, cycling, tennis, rounders, boating, hockey, to say nothing of fishing, shooting, yachting, hunting, and, greatest wonder of all, she has, in many cases, taken seriously to walking. All this means that a change for the better in mind, as well as in body, is registered on the bronzed cheeks of the modern damsel. The "vapours" of our granddames are dead as Queen Anne, fainting has gone out of fashion, and the average maiden of to-day moves, sleeps, and eats like a healthy human being. Clothing, too, must be in time brought to a rational standard, for no woman living could endure the martyrdom of a long walk for two successive days in shoes with high heels and pointed toes. If the medical profession were not guided by motives of the highest philanthropy they would not encourage this ruddy-cheeked movement, for it robs them of a lucrative field of practice.

Lay Views on Cancer.

A GREAT discussion on cancer is at present raging in the columns of an evening contemporary—the Echo. Presumably it is only necessary to mention the name of this paper in order to afford some idea of the character of the discussion to which publicity is being given. In its former, and we think better days, the Echo did good service in trying to educate the masses in progressive science and in taking the lead in improving the minds of those who looked to its columns for instruction. But latterly, we are sorry to note, the policy of the journal has become that of cranks, to whom reasoning beings pay but little heed, Among other things that the cranks have done for the Echo is to have turned it into spiteful anti-vaccination organ, a virulent opponent to vivisection, and a persistent and unfair traducer of the medical profession. cal men do not care, of course, what the readers of the Echo think of them, but it is a poor, pitiable policy for any enlightened editor to adopt of making capital out of slanderous attacks upon a body of professional If anything scurrilous can be said of the practice of medicine, or of its followers. there always seems to be an opportunity of giving it publicity in the columns of the Echo. In the discussion to which attention is drawn above medical men are greatly blamed for not having discovered the cause of cancer and the means of curing it. Again, instances are related by correspondents in which cancer has been cured by persons not in the profession when medical men have pronounced an unfavourable prognosis. It is, of course, scarcely needful to point out to the editor of our contemporary that all such statements should be received with much caution, and especially the announcement that there is an establishment at Berne which has a world-wide reputation for curing all cases of cancer, save those in which the throat is involved. The exception is a brilliant concession to public opinion, in view of the sad ending of the late Emperor of Germany, from carcinoma of the larynx.

The Dum-Dum Bullet Again.

THE Peace Congress at the Hague last week, stultified itself by passing a resolution to the effect that the Dum-dum bullet must be prohibited in modern warfare. The effects of this bullet have been discussed and commented upon ad nauseam and military experts, with personal experience of its use, have repeatedly proved that the objections urged against the missile, have been founded upon a misconception of the damage it inflicts. We should not have referred to the subject again, save for the purpose of pointing out that the discussion upon it at the Congress clearly shows that those who voted for the prohibition of the bullet could have had no personal knowledge of the matter. Again there has never been the slightest intention on the part of the authorities of ever using the bullet against any European troops with which we may be engaged. The bullet was designed merely for the object of crippling the "rushing" power of savage tribes, upon whom the projectile of the modern rifle had been proved to have but little effect. The case is recorded of an Indian native who received sixteen bullet wounds caused by a Lee-Metford rifle, during the Chitral expedition, but despite this he made a good recovery. Before the other European Powers take upon themselves to condemn the Dum-Dum bullet, it would. perhaps, be better for them first to try the effects of their own service rifle projectiles against a tribe of savages in warfare, and arrange for the results to be recorded by any of their troops who may happen to survive. However, it would then probably be too late to recognise that the Dum-Dum bullet was necessary in such engagements.

Pauper Classification.

THE spirit of dead official conservatism is nowhere more marked than in the treatment of the Poor-law population. After years of public agitation and scandal a departmental bill was issued and things straightway go on as before, to quote the words of a well-known song, "it may be for years, or it may be for ever." For instance, on January 1st, 1895, an order is issued from the Home Office, advising the classification of paupers. Now, four years later, a species of shock of galvanising wonder has run through London at the news of definite action by a board of guardians on the lines of that official monition. Fulham, to its honour be it said, has started large separate wards for a number of aged inmates who have come to want through no fault of their own. They are all over 65 years of age, and many of them have at one time been ratepayers in the parish. They now have greater freedom, better quarters, and an increase of privileges and comfort all round. Their dietary, owing to stern official rule, cannot be improved, but it is to be hoped that the Home Office will amend the bye-laws in that direction. This fresh departure is one of the most promising of recent years by way of humanising the terrors of a rigorous system. It has taken four years for a single Board to carry out the desires of the central governing body. We wonder how long it will take to put in force Mr. Chaplin's famous departmental order for the separate nursing and care of the crippled pauper children of the metropolis.

Poisoning by Belladonna Plaster.

THE occurrence in the provinces of a case of pojsoning by means of the absorption of belladonna from a plaster reminds us of the still uncertain composition of those applications. One of the notable features of the recent revision of the British Pharmacopæia was the standardising of the emplastrum belladonnæ. Before that time the alkaloidal strength of the commercial product varied within wide limits from a mere trace up to a considerable potency. The only firms we believe that had consistently standardised their plasters were Messis. Mather and Co. of Manchester, and Messrs. Seabury and Johnson of New York and London, and we fancy that fact has hardly been widely enough recognised among the medical profession. Belladonna, when applied in the form of a sound and trustworthy plaster, is of the utmost value in treatment of many painful the affections and in the arrest of the mammary and other secretions. Its practical value, however, has always been discounted by the variability of its composition, and many a surgeon has given up the plaster as worthless simply and solely because he has been using a preparation containing only the merest trace of alkaloid or none at all. In future, however, all that is to be changed. That is to say, when one or two little obstacles have been surmounted. First and foremost, when the worthless stocks have been Next, when local authorities take the trouble to supervise the purity of drugs vended to the public.

Apprenticeship to Apothecaries in Ireland.

A QUESTION of much importance to the Irish Apothecaries' Hall has been raised, last week, by an application for a mandamus by a student named Miller to compel the Pharmaceutical Society to admit him to their Licence examination. This young gentleman served the necessary apprenticeship to Dr. Forsythe, a Licentiate Apothecary, but the Pharmaceutical Society rejects that service as qualification for their examination. The point is, that though Dr. Forsythe is undoubtedly a L.A.H., he did not obtain that qualification under the original Apothecaries' Act of 1791 (which prescribed an elaborate education and examination in pharmacy), but under the Medical Acts of 1858 and 1886 which made the curriculum and examination mostly medical and but slightly pharmaceutic. The Court granted a conditional order for the mandamus, but, of course, this only means permission to the lawyers to earn second fees by arguing out the point on a future occasion.

Medical Practice in Kashmir.

DR. NEVE, writing in the Indian Medical Gazette refers to the various forms of disease met with in Kashmir, and the list is an interesting one from several points of view. In the first place, despite the fact that the country is little more than an alluvial plain during the summer months, malarial disease is quite rare, owing no doubt to the altitude. But diseases of the eye are very numerous, especially ophthalmia and entropion, nevertheless cataract is much less common than in the plains. Curious to relate, skin affections of parasitic origin abound scabies being universal. Again, dyspeptic troubles are very frequent, the cause being attributed to the excessive quantities of starch consumed in the form of rice. Commonly also dilatation of the stomach is met with. Another feature of note is the absence of scarlet fever and diphtheria, and the rarity of phthisis, save in those who lead indoor lives amid unhygienic surroundings, such as shawl-weavers. Rickets, again, is a disease which is seldom seen, but rheumatism is very prevalent, and Dr. Neve also mentions that during the past year, 2,918 operations were performed at the Kashmir Mission Hospital, and that of these no fewer than 462 were for entropion; on the other hand, there was only one case of ovariotomy, and that terminated successfully.

A New Treatment for Tuberculosis.

DR. KARL VON RUCK has introduced a new method of treating cases of pulmonary tuberculosis, namely that of the injection of a fluid extract of tubercle bacilli. In 78 cases thus treated he claims that 64.1 p.c. were cured and 33.3 p.c. improved. The serum prepared by his method differs materially from that known as Koch's Tuberculin R. If von Ruck's treatment should prove to be as serviceable in the hands of others as it has proved in those of its author, the promoters of the open-air treatment of phthisis in this country will have to reconsider their position. But a good deal of confirmatory evidence will be needful before the infection of a tuberculin as a cure for pulmonary tuberculosis will be able to convince the profession in this country of the efficacy of the method, and until Von Ruck has fully supplied the data in this regard it would be premature to speak with any enthusiasm upon the subject.

Infectious Disease Difficulties at Nantwich.

SEVERAL points of practical importance have recently been raised at the Nantwich Board of Guardians. In the first case two patients suffering from typhoid fever were removed to the Isolation Hospital, Crewe, where the clerk called upon Dr. Atkinson to attend them in his capacity of Medical Officer of Health. The patients were paupers from another union, and Dr. Atkinson naturally asked for payment for his attendance. After a good deal of discussion the guardians wisely decided to grant "reasonable remuneration" for the special service. It would be well for all public health officers to resist the demands for purely medical services which are made upon

them by various local authorities from time to time, usually with regard to attendance on persons engaged in parish work. The second case was that of a farmer who sent a lad in his employ suffer ing from scarlet fever to the Isolation Hospital. This step he had taken, so he claimed, in the interests of the public, and he applied to the Rural District Council to pay the hospital expenses, for which he had become responsible on the lad's admission. The Council decided by a large majority to refuse to pay any portion of the cost. This decision will hardly encourage other dairy farmers to send off to the hospital any of their employees who may be attacked by communicable disease. There is a good deal to be said in favour of making a general charge of what confers so direct and essential a benefit upon the public.

Professor Osler, M.D., F.R.S.

PROFESSOR OSLER, of the Johns Hopkins University, Baltimore, has just arrived in England, and on the 16th instant he will deliver the Cavendish Lecture before the West London Medico-Chirurgical Society, the subject being cerebro-spinal fever. On the 15th instant the President of the Society, Dr. Clippingdale, will entertain at dinner Professor Osler, together with the President of the Royal College of Physicians (Dr. Church), the President of the Royal College of Surgeons (Sir William MacCormac), the Council of the Society, and other guests. On the 22nd instant, Professor Osler will be the guest of the staff of the West London Hospital at the Past and Present West London Hospital Dinner, which will be held at the Trocadero Restaurant. The dinner, which was a great success last year when it took place for the first time, promises this year to eclipse its record, and it is expected that an attendance of 200 at least will be reached.

The Case of the Late Mr. Hunter.

THE long-promised discussion at the General Medical Council on the peculiar circumstances under which the Council ordered the prosecution of the late Mr. Hunter, L.S.A., for styling himself "physician," proved a very mild affair. Admitting that the Council, as a whole, was not cognisant of the exact circumstances under which the proceedings were to be taken—an inexplicable and even unpardonable omission on the part of the Penal Cases Committee -it is stated that Mr. Hunter himself was anxious to have the point cleared up, and had expressed his willingness to defend his action in the matter. We may take this assurance with the proverbial grain of salt, and the same cautious procedure may be applied to the statement that it was really a sort of friendly suit, in which both parties mutually assisted each other in obtaining a formal judicial pronounce-The Committee regarded it as a test case to establish the law in respect of the use of the Philadelphia degree, but, as a matter of fact, the legal arguments turned exclusively on the point whether a licentiate of the Society of Apothecaries has or has not the right to dub himself physician. However we look at it the point was worth clearing up, and however much we regret the tragic element imported into the case by the death of the defendant, and deprecate the somewhat curious circumstances under which the proceedings were authorised, we are pleased that a definite statement has been obtained. We should even like to see this matter pushed to its logical conclusion, for nothing is more irritating than the sempiternal disputes as to the titulary rights of the various orders of medical practitioners. If there be any special rights by all means let them be defined; if there be none, then let us cease to haggle about trifles.

Medical and Clerical Enterprise.

At the Church of All Saints', South Merstham, a notable illustration of the old proverb, "Cleanliness is next to godliness," occurred on Sunday last, for the vicar of the parish secured as a special preacher a member of the profession, who resides in the medicoaristocratic locality of Queen Anne Street, Cavendish Square. The fact that this arrangement of his pulpit would obtain was announced by the vicar to his parishioners in the following manner:-"I feel that it is almost a farce to come and talk to some of you on spiritual matters when all the while my fingers itch to open or clean your windows, scrub your woodwork, and wash your children. So thinking that perhaps you would pay more attention and give more heed to what a doctor of medicine says I have asked, by special permission of our Bishop, a clever friend of mine, who has knocked about the world a good deal and seen a lot of life, to come down from town and talk to us in Church next Sunday evening after the prayers are ended on 'Cleanliness is near Dr. Usher, of Queen of kin to Godliness.' Anne Street, Cavendish Square, W., who is a specialist in his own particular line "-what line-" and is a most entertaining man and interesting speaker, will talk on the Gospel of Fresh Air, leaving beds open to the air, washing bodies all over as well as just face and hands, washing blankets as well as sheets, flushing drains, not letting the tea stew on the hob and so bring on indigestion, and other inducements to taking a nip 'too often.'" This is certainly a novel departure in the promotion to the gospel of health. Obviously it is capable of many developments. In time, perhaps, we shall see an announcement in the Times to the following effect: "At the special invitation of the Dean of St. Paul's Cathedral, Sir Bouncing Fitzblazes, M.D., F.R.S., will preach at the usual afternoon service on Sunday next, 'On the modern methods of feeding babies.' A collection will afterwards be made for the benefit of the 'Go-Cart League,' for providing go-carts for the poorer classes in London whose means do not permit of the purchase of this necessary appliance for enabling infants to become acquainted with the enormous traffic of the metropolitan thoroughfares." Doubtless other possible deve-

lopments in the same direction will occur to our readers.

Liquefied Hydrogen.

THE fairyland of science is nowhere more wonderful and attractive than in the province of chemical research. It is hardly too much to say that almost all the great advances of modern science have had their origin, directly or indirectly, in the test tubes and phials of the chemical laboratory. Ever since the days of Faraday and Sir Humphry Davy, workers in this fascinating branch of exact investigation have been seeking for some means of liquefying The difficulties in the way have been hydrogen. enormous, but they have at length been overcome by the patient genius of Professor Dewar, who announced his discovery last week at the Royal Institution Liquid hydrogen, he pointed out, was not only a precious and costly substance, but it was exceedingly volatile and had to be preserved with great care. In order to protect it as much as possible from radiation he surrounded the product with liquid air. The physical qualities of liquid hydrogen are of a striking character. Thus it is non-magnetic and the specific gravity is such that a piece of cork placed in it immediately sinks to the bottom. The temperature at boiling point was 21 deg. absolute, or sufficient to yield a pressure described by the discoverer as "unmeasurable." By its agency a vacuum could be produced of so perfect a nature that mercury distilled upwards. There can be little doubt that in the hands of this distinguished investigator the liquefaction of hydrogen and the introduction of a new agent have proved a distinct triumph of practice as well as of theory. Many distinguished men of science who were present at the lecture expressed their belief that the discovery was an invaluable one, and marked an era in the history of chemical investigation.

The Stanley Hospital at Liverpool.

THE journalists of Liverpool have recently raised on high the voice of lamentation over the waning fortunes of the Stanley Hospital. Founded in 1867, on a site given by the late Lord Derby, the institution has steadily grown in size. The present movement is designed mainly to pay off debt, to add to the number of beds, and to build a nurses' wing. objects are doubtless desirable in themselves, but we should like to hear something more of the means that are taken to prevent the charity of the Stanley Hospital from being bestowed upon improper subjects for medical relief, that is to say, upon persons who are able to pay private practitioners. We say this without any special knowledge of the Stanley Hospital, which we believe to be an excellently conducted institution, but we take it as the apparent type of charity whose capacity for funds and for patients at any price is limitless. The Liverpool Post writes as follows:-"Perhaps no better test of the development of the hospital can be adduced than the figures submitted in last year's report, which show that whilst in 1867 the total number of attendances during the year was

10,618, they in 1897 had increased to 53,534, and that whilst in 1878 there were 241 in-patients, these in 1897 numbered 1,047." We should like to hear what steps are taken to exclude patients who are able to pay moderate fees or whose ailments are so slight as not to require hospital treatment. Some day the medical charities will learn that it would have been better to cultivate the friendship of the general practitioner. If we mistake not the consultants on the staff may have some reason to regret that they also have not paid more attention to the demands of their outside brethren.

The Notification of Phthisis in Manchester.

THE Manchester Corporation have taken an important step in regard to the notification of phthisis within their jurisdiction. It has been agreed to make the disease a notifiable one, and to appoint a medical officer with a salary of £200 per annum, whose duties will consist in visiting the notified patients at their homes, investigating the circumstances under which the disease has been contracted, and the conditions and arrangements of the infected houses. On the report of this official steps will be taken to carry out the necessary measures of disinfection. It will be with much interest, doubtless, that the sanitary authorities throughout the country will watch the result of this new development in notification. However illadapted the Notification Act may be for Ireland, it is nevertheless certainly true that its enforcement has been beneficial in England.

Tetanus in Jute.

An inquiry into the cause of death of a worker in a Dundee jute factory elicited, last week, statements which, if true, have the highest significance as to the pathogeny of tetanus. The operative had injured her foot in a jute mangle, and died of lockjaw five days afterwards. The inspector of factories stated, on examination, that he had taken to London samples of the dust from below the mangle, and that upon bacteriological examination it was found to contain considerable quantities of the tetanic spore. He said, furthermore, that though there has been as yet no record of a connection between jute and tetanus, it seems quite possible that this particular jute, which came from Bengal, was capable of developing the bacillus rapidly, inasmuch as all the climatic conditions of Bengal are favourable to such development.

A Pronouncement in Medico-Dental Ethics.

BE it known to all whom it may concern that the General Medical Council, in solemn conclave assembled, have adopted the recommendation of the Dental Committee stigmatising as "infamous conduct in a professional respect" any assistance rendered by a registered medical practitioner to an unregistered person in the performance of a dental operation or by administering an anæsthetic "or otherwise." In future it will be incumbent on all practitioners before consenting to assist anyone practising as a dentist to assure himself that he or she has been duly registered, failing which precaution they may

attain some unenviable and uncomfortable notoriety. We have nothing to say by way of adverse criticism in respect of the Council's determination, which is only the logical outcome of its policy in respect of the repression of covering in all its forms.

St. Mary's Hospital, Paddington, Bazaar.

A SUCCESSFUL bazaar was held on two days last week in aid of the funds of St. Mary's Hospital, Paddington. It was entitled a "Streets and Squares Bazaar," because a series of local committees was organised representing the various streets and squares in the neighbourhood of the institution. The sum of £70,000 is needed for the completion of the new Clarence wing, and towards this a substantial amount was netted as the result of the Bazaar.

Artificial Cardiac Disease for Malingerers.

Several members of the medical profession in the Rhenish district have been arrested for having supplied to conscripts in return for heavy bribes, cardiac depressants in order that they might be rejected by the military authorities when physically examined. The domiciliary visits of the police to the houses of these practitioners are stated to have revealed plenty of incriminatory correspondence.

SIR THOS. GRAINGER STEWART, Professor of Medicine in the University of Edinburgh, who went to Berlin as the representative of the University at the Congress on Tuberculosis has returned home-Report has it that he was singled out by the Emperor for a private conversation,

Scotland.

FROM OUR OWN CORRESPONDENT.

THE GENERAL MEDICAL COUNCIL AND PEELIMINARY EXAMINATION.—The Council in their recent session has been considering, amongst other business, the necessity and advisability of raising the standard of the preliminary examination, but has found it a really difficult In G settle. Glasgow the business to standards attained by young lads leaving school now is said to be lower than it was some years ago, and one of the examiners in English has stated that attained school the average paper written by candidates for the medical and arts preliminary is a shocking production. Many of the candidates are unable to put together a few con-nected sentences into grammatical English — the tendency of schools being towards the teaching of Latin, Greek, Mathematics, German, French, &c., instead of the mother tongue. In such cases "Keys come in handy," which help the candidates to cross the rubicon, and so enter into the pleasant paths of the coveted and noble medical profession, and in due time attain to the dignity of "professor," for a deficiency of knowledge of the English language is no bar to a professoriate.

Women on Hospitals and Local Boards.—After a largely attended meeting recently held by ladies for the promotion of the return of women to local boards, a letter has been sent to the directors of the infirmaries and hospitals in Glasgow, in which they are allowed one month to decide whether or not they are willing to concede the principle of female representation on the directorate of the various institutions. A committee consisting of ladies, ministers of religion, and a Sheriff, has been appointed to confer with the

directors of the infirmaries on the subject, and to assist in the selection of lady representatives in the event of the principle being conceded. In their communication to the directors the committee make it plain that a rebuff or refusal will not end the agitation, stating distinctly that the matter will be brought to an issue at the first annual general meeting of each institution and successive general meetings until their object is attained. The grounds on which the demand for female representation are made are chiefly (1) That it would tend to make the household management of hospitals and infirmaries more efficient. (2) That as regards women and children a lady should have the responsible power given her of personally seeing to their needs, and of bringing suggestions before the board that such patients would more readily communicate matters which That a lady on the board would be able to communicate more freely with nurses than any man on the board would, to some extent, relieve the matron the board would, to some extent, relieve the matron of entire responsibility; such responsibility at present in certain cases is not wholly desirable, and some matrons would be glad to be relieved, to some extent, of their pre-sent complete responsibility. We fail to see how ladies will be able to know more the wants and needs of the women and children patients than at present. What is the use of nurses, resident medical officers, superintendent and matron in an infirmary or hospital, unless it be to minister to the needs of patients under their charge? Even supposing the ladies gain their point and are admitted on the boards, their information regarding patients must be obtained through present channels and sources. If these ladies can find out and suggest ways by which our present extravagant methods of conducting and committee on the conducting and conduc conducting and carrying on our infirmaries can be reformed, they will be doing something really of importance and value, but when they suggest to relieve matrons of some of their responsibility we do not quite grasp their intention, unless it be to make both matrons and nurses subordinate to their wills, and ultimately to suggest that female representatives should have entire control of female patients and children, as well as participation in regard to male patients. Glasgow ladies are evidently following the lead of the Edinburgh ladies, of whom there are two on the directorate of the Edinburgh Royal Infirmary.

Correspondence,

We do not hold ourselves responsible for the opinions of ou correspondents.

THE VICE-PRESIDENCY OF THE ROYAL COLLEGE OF SURGEONS OF IRELAND.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

Sis,—Inasmuch as there was no change in the offices of president or vice-president in this June election, which took place to-day, I desire to inform the Fellows of the College that last year, when I expressed to the electors my determination to offer myself for the office of vice-president, I felt that my long service to the School and College as senior demonstrator, examiner and councillor, and my seniority as a surgical teacher and as a hospital surgeon, might reasonably deserve recogni-tion by the Fellows, and that I might hope to be honoured with election to the office I then sought. happily personal and domestic circumstances prevented me from giving prominence to my candidature until others had occupied the ground in some degree, and as a contest is extremely distasteful to me, and in my opinion is not to the advantage of the College, I thought it best to refrain from presenting myself for the vicechair until the next legitimate vacancy occurs in June, 1900. I desire, however, to assure the Fellows that under any circumstances I shall do so when that time arrives. With this intimation, I trust that my friends and supporters among the Fellows will not be induced

to pledge their votes to any other candidate for the next vice-presidency.

I am, Sir, yours truly, L. H. Ormsby, M.D., F.R.C.S.I.

92, Merrion Square, Dublin, June 7th, 1899.

ENURESIS.

To the Editor of THE MEDICAL PRESS AND CIRCULAR. Sir,—In answer to your correspondent who has asked suggestions for the relief of this troublesome malady, many cases of night incontinence of urine have come before me at the public dispensary. I have followed Trousseau's treatment with belladonna, often combining the belladonna with iron if the patient were ansemic, and with bromides if hysterical. I took care to keep the bowels regular, and to act generally on the gentle tonic regimen in relation to cheerfulness and general employment and mode of life.

But in addition to such wide general principles, I insisted that the patients should sleep, even in some cases going to bed for one hour or more at mid-day. Every employment or duty was to be subordinated to a genuine

sound mid-day sleep of one hour at least.

The results have been most gratifying, e.g., a girl, æt. 17, who had wet the bed every night since she was a child, was permanently cured in a week. Many such cases have presented themselves and been cured.

I am, Sir, yours truly,
WILLIAM H. PEARSE, M.D.

Plymouth, June 7th, 1899.

THE APPOINTMENT OF POOR-LAW OFFICERS BY THE BRADFORD BOARD OF GUARDIANS.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,-Your issue of May 24th ult. contains a memorandum upon the above subject from Dr. Crowley and Mr. Hall.

The third paragraph of the communication reads as follows:—"The Committee of the older Society (Bradford Medico-Ethical) has met and discussed these appointments, and decided that no steps should be taken in the matter."

The Committee of the Bradford and District Medico-Ethical Society take exception to the form of the above statement, and to prevent a wrong inference being drawn from it, we are instructed to forward to you the following extract from the minutes of the committee meeting referred to:-"The question of the proposed appointments by the Guardians of the Bradford Union of Dr. Crowley and Mr. Hall was discussed, but as there was a probability of a meeting of the profession being called by another society, no resolution was passed. The committee were, however, strongly opposed to the character and manner of the appointments.

We are, Sir, yours truly, W. Horrocks, Hon. Secs. A. Manknell. Bradford, June 10th, 1899.

Medico-Legal Aotes. By W. J. JOHNSTON, B.L.,

Adulteration of Food.

THE decision of the Queen's Bench Division in Shortt Robinson (8 L.T.R. 261) is an interesting illustration of the working of the Food and Drugs Act, 1875. The facts have already been reported, but we may summarise them shortly as follows. A grocer was charged under Jection 6 of this Act for selling caper tea which was alleged to be adulterated. It was proved by the county analyst that the tea contained 3.5 per cent. of foreign matter, and the prosecutor asked for a conviction The justices, however, stated as a fact within their own personal knowledge that caper tea was grown on friable, sandy soil, under circumstances which rendered frequent and copious showers of rain necessary, and was therefore likely to contain a certain amount of mineral matter. They thought that, under these circumstances, 3.5 per cent. of such matter was not excessive, and refused to convict. A case was stated for the opinion of the High Court, and the question was argued whether the magistrates were entitled to take cognisance of facts which were within their own personal knowledge, but which were net proved in evidence. The Queen's Bench Division held that the justices were so entitled in this particular case, and refused to interfere with what had been done in the Court below.

CONSCIENTIOUS OBJECTIONS TO DOCTORS.

The well-known and oft-quoted passage from St. James's epistle, "Is any sick among you? Let him call for the elders of the church," has had a curious history in the law courts. The case of Reg. v. Senior (47 W. R. 367) is the latest stage of this history, and arose on the interpretation of Section 1 of the Prevention of Cruelty to Children Act, 1894, which declares that any person who, having charge of any child under sixteen years of age, wilfully neglects such child in a manner likely to age, wilfully neglects such child in a manner likely to cause it unnecessary suffering, shall be guilty of a misdemeanor. The child in question was suffering from diarrhea and pneumonia, which ultimately caused its death, and the father, who belonged to a sect called the "Peculiar People," and had conscientious objections to doctors and drugs, refused to call in medical aid. The medical evidence was that the child's life would certainly have been prolonged, and might probably have been saved, if medical assistance had been procured. Was the father, who otherwise had been kind to his child, guilty of "wilfully neglecting" his child within the meaning of the statute? Mr. Justice Willes held that there was evidence that he was, and left the sufficiency of the evidence as a question to the jury. When the question was argued before the Court for Crown Cases Reserved, Lord Russell said that "wilfully" in the section meant deliberately, and not by inadvertence, and that "neglect" meant the omission to do something for the benefit of the child. In other words, "intentional failure to take those steps which the experience of mankind shows to be generally necessary." In the result, the conviction of the prisoner at the trial was upheld. The case amounts to a decision that the deliberate omission to call in medical aid, on account of honest, conscientious belief, is wilful neglect within the meaning of the section.

AT COMMON LAW.—Before there was any legislation on this subject the rule seems to have been different. An instructive case on the point was Reg. v. Wagstaffe (10 Cox C. C., 530), which was a decision of Justice Willes. In that case, the prisoners, who were the parents of the child, had conscientious objections to calling in medical assistance, honestly believing that God would heal the sick child. They also belonged to the sect of the "Peculiar People," and founded their belief on the same passage in St. James's epistle. As a result of the illness the child died, and at the trial of the parents the judge told the jury that the mere omission to provide medical advice under the ciriumstances, when the objection to do so was honest and not a mere blind or screen for misconduct, was not culpable homicide. This seems to have been the rule at common law.

LEGISLATION ON THE SUBJECT.—The Act of 1868 (31 and 32 Vic. c. 122, s. 37) provided, among other things, that any parent who wilfully neglected to provide medical aid for his child, thus causing the health of the child to be seriously damaged, should be guilty of an offence. The decision of Reg. v. Downes (1 Q.B.D. 25), made it quite clear that when a person intentionally and deliberately abstained from providing medical aid, knowing it to be obtainable, he was guilty of an offence under this Act, and the motives which operated on his mind did not save him from the results of his conduct. This section was repealed by the Act of 1894; but although the words "medical aid" are left out of the latter Act, it is still the duty of a parent, according to Lord Russell in Reg. v. Senior, to provide medical aid for his children, and the omission to do so is wilful neglect.

(To be continued.)

STEPHENSON'S NEW POISON BOTTLE.

The ingenuity of inventive geniuses has, for some occult reason, been largely devoted of late to the subject of poison bottles, i.e. bottles which by reason of roughness of surface, oddity of outline or general unshapeliness can be distinguished from ordinary medical bottles even in the dark. One of the simplest—and therefore one of the best, seeing that simplicity is of importance—is that submitted to us by the makers. Mesers. Hearns, Limited, Lea Bridge Glass Works, N.E. It is made of blue glass, bearing the word "Poison" in raised letters, and its distinctive feature is a pinching in of the waist, giving it, roughly speaking, the outline of a fashionable lady. This gives a firm grip, and renders it absolutely impossible to handle without becoming conscious of its peculiar shape. Any person taking poison out of such a bottle even at dead of night might reasonably be adjudged felo de se without further inquiry. The price is not notably higher than the ordinary death trap poison bottle, guaranteed to deceive at first sight.

Medical Rews.

The Royal Orthopsedic Hospital, London.

A MEETING of the governors of the above Institution A MEETING of the governors of the above Institution was held at 20, Hanover Square on June 8th, under the Presidency of Lord Wantage. The five re-elected members of the old committee brought forward propositions for five alterations of rules. The first four changes were carried without opposition from the members of the new committee, but the fifth involved a good deal of discussion and voting. Briefly, the four unopposed resolutions provided that the time qualification for a governor's vote, and for membership of the committee, should be twelve instead of six months; that the committee should have power to add to their that the committee should have power to add to their number, and that a fortnight's notice of candidature for committee should be given to the secretary. The meeting appeared to get out of the control of the noble chairman at an early period, but it must be said that most of the strong language came from the old commost of the strong language came from the one of the mittee, who repeatedly characterised the movement for reform as a "raid." On the other side Mr. Marks and Mr. Parker admitted that they had organised the voting that ousted the old committee as the only means of obtaining urgent and necessary changes of administration. Their chief grounds were that no effective steps had been taken to remedy the unsanitary condition of the hospital, although it had been notorious for many years past, and had led to recent deaths, besides causing the grant from the Prince of Wales' Fund to be withheld. The old committee had allowed income to dwindle and expenditure to increase. They had proposed to sell the hospital site for £28,000, whereas an independent authority, Sir Whitzker Ellis, valued in £28,000. at £36,000. Not one of these points was seriously shaken by the members of the old committee, which included Sir Walter Gilbey, Sir Ernest Clarke, Alderman Bell, and Mrs. Drower. Indeed, the only point scored by them was the modification of a statement of Mr. Parker's that the old members had not helped the new, which was altered to the extent that two of the old members had latterly helped the new executive. The old members made free use of such terms as "raiders," "absolutely false," and of other equally emphatic language, but the climax was reached by Alderman Bell who, in moving the fifth resolureached by Alderman ben who, in moving the first resolu-tion made an extremely bitter and personal attack on one of the honorary medical staff, Mr. Reeves, whom he designated as an "arch-conspirator." The alteration last-mentioned was to the effect that no medical officer of the hospital shall be eligible for election as a member of the committee of management. On being put to the vote this was lost by a large majority. Both sides then produced a number of proxies, and in the upshot the old committee carried their point by a small majority. The re-elected members of the old management, Sir Walter Gilbey, Alderman Bell, Sir Ernest Clarke, Mr. Drower, and Mr. Studd, then handed in their written resignations to the Chairman, Lord Wantage, who intimated his own resignation.

Summer Trains de Luxe.

IT may be of interest to some of our readers who may intend visiting one or other of the Continental Spas, or are sending patients thereto, to know that the International Sleeping Car Company has commenced running the Carlsbad Express daily to Frankfort, Bayreuth, and Carlsbad direct from Ostend in connection with the 10 a.m. services from London.

The Engadine, Interlaken and Lucerne Express will commence running from Calais on the 8th July until the end of the season, in connection with the 11 a.m. ser-

vices from London.

A new Train de Luxe, to be called the Royan Express, will, from 8th July until 12th September, run from Paris (Gare d'Orleans) direct to Niort and Royan every Monday and Wednesday, starting at 7.50 p.m., corresponding with the 11 a.m. train from London.

The Luchon Express will leave the Gare d'Orleans every Tuesday and Thursday at 7.32 p.m., commencing on June 27th. From July 22nd until August 19th inclusive the Luchon Express will run on Mondays also. These trains are composed exclusively of the Company's sleeping, restaurant, and baggage cars. The official guide of the Company, "The Continental Traveller," containing full particulars as to times and fares, is sent post free to intending passengers, from the London offices, 14, Cockspur Street.

The Medical Sickness and Accident Society.

THE sixteenth annual meeting of this Society was held in the rooms of the Medical Society of London, Chandos Street, W., on Wednesday, May 24th, 1899. The chair was taken by Dr. De Havilland Hall, chairman of

Drs. A. S. Gubb, Dr. Walter Smith, Dr. F. J. Allan, Dr. J. Pickett, Dr. Knowsley Sibley. Mr. Brindley James, Dr. J. B. Ball, Dr. J. C. Williams, Dr. Percy Jakins, Dr. Leonard Grant, Dr. Miller, Dr. Barkwell, Dr. Clibborn, Dr. Owen, Dr. Culling, Dr. Bateman, Dr. Freeland, Dr. Rainsford, Dr. Cahill, Dr. Evans, and Dr. W. W. Hall.

The Chairman said that on the eightieth anniversary of their beloved Sovereign's birth he was only expressing the wish of all present in hoping she might yet be spared many years to rule ever her people for whom she had done so much. As medical men they ought to be espe-cially grateful for the example she had set in her rela-

tions with the medical profession.

He congratulated the Society on the year's work, on the smooth manner in which their business was carried on, and on the regular attendance of the Executive Committee. The Society was steadily growing. During its fifteen years' work it had paid over \$240,000 in sickness benefits, and including the present surplus, returned over \$210,000 in sech honoress. By economy of working a considerable cash bonuses. By economy of working a considerable surplus had been produced in the management fund, and a special reserve had been created to cover any fluctuation in the value of the investments. The valuation had been based on the low rate of 2½ per cent., and a special reserve created against chronic sickness, the relief of which was, in his opinion, one of the most important functions of the Society.

There was a trifling surplus in the Life Assurance Fund and an insignificant deficit in the Annuity Fund, and he felt sure that the Society had acted wisely in ceasing to undertake fresh business of this kind, and in obtaining better terms for the members by acting as

agents for the Rock Life Office.

With regard to the suggestion that the surplus should be applied to the extension of the sickness benefit from age 65 to 70 he read figures showing that it would be quite insufficient for this purpose and pointed out that the increase of average sickness after age 65, was much greater than was generally recognised. For any such extension a separate fund would have to be formed, and the necessary contributions to it would be of considerable amount. He concluded by expressing the thanks of the Society for the aid they received from the medical press, and in particular from the British Medical Journal and the MEDICAL PRESS AND CIRCULAR, and hoped that in this way the membership would be increased until it reached a total of at least 5,000.

The report was unanimously adopted and the distribu-

tion of a 10 per cent. bonus agreed to, and the proceedings closed with a vote of thanks to the Chairman.

Indian Medical Service.

THE annual dinner of past and present members of the Indian Medical Service took place in the Victoria Hall, Hotel Cecil, on Thursday last, Surgeon-General Sir W. Guyer Hunter, K.C.M.G. in the chair, supported by Sir Henry F. Norbury, K.C.B., Director-General of the Naval Medical Department, and Surgeon-General J. Jameson, C.B., Director-General A. M. S., Sir Joseph Fayrer, Bart., and many other distinguished officials. The thanks of those present were accorded to Dr. Freyer for the admirable way in which he had organised the meeting, which Dr. Freyer acknowledged in appropriate terms.

A Cancer Society,

A MEETING was held in St. Martin's Town Hall, London, on the 7th inst., with Sir Charles Cameron in the chair, to inaugurate a society having for its objects the prevention, amelioration, and the cure of cancerous disease. There was but a small attendance, but if anything can be done to assist in staying the ravages of this disease, support will not be lacking. Dr. Herbert Snow followed with a paper which we hope to publish in our next.

Royal College of Surgeons in Ireland.

AT a meeting of Fellows held June 5th, the following were elected for the ensuing year:-

President-Robert Lafayette Swan.

Vice-President—Thomas Myles.

Secretary—Sir Charles A. Cameron, C.B.

Council—Archibald H. Jacob, Edward Hallaran Bencouncil—Archioaid H. Jacob, Edward Hallarah Bennett, Sir Philip Crampton Smyly, Sir Thomas Stokes, Henry Rosborough Swanzy, Wm. Stoker, William Ireland Wheeler, Sir William Thompson, Austin Meldon, D.L., Sir Charles A. Cameron, C.B., L. Hepenstal Ormsby, Richard D. Purefoy, John J. Cranny, Henry Gregg Sherlock, John B. Story, Henry Fitzgibbon, Francis T. Heuston, John Lentaigne, and Richard Bolton M'Causland.

Isolation of infectious Disease.

THE following important case was heard and decision given in London by Justices Day and Lawrence in the Queen's Bench Division last week. The case was a special appeal case from the decision of certain justices of Workington, Cumberland, and raised a point of considerable importance under Section 124 of the Public Health Act. Mr. Macmorran, Q.C. in support of the appeal, said Section 124 of the Public Health Act, 1875, ran as follows:—" Where any suitable hospital or place for the reception of the initial content of the section of sick is provided within the district of a local authority, or within a convenient distance of such district, any person who is suffering from any dangerous infectious disorder, and is without proper lodging or accommoda-tion, or lodged in a room occupied by more than one family or is on board any ship or vessel, may, on a certificate signed by a legally qualified medical practitioner . . . be removed by order of any Justice to such hospital or place at the cost of the local authority." It appeared that the cost of the local authority. It appeared that the respondent was a labourer residing with his wife and seven children in a small house of four rooms. One of the children was attacked with scarlet fever, and though it was properly nursed and had adequate medical attendance, the local authority applied for an order to remove the child to the hospital, in order that it might not be a danger to the other inmates of the house. The Justices refused to make the order, holding that "proper lodging accommodation" ought to be decided with reference to the wants of the person infected. He (the learned Counsel) submitted that the words must have reference to all the surroundings of the case, and one of them was that if the child was not removed it was likely to be a danger to other persons in the house. There was no reflection on the parents, who had provided for the child to the best of their means.

Mr. Justice Day said in his opinion the Justices ought to have made an order for the removal of the child. Therefore the case would be sent back to them,

Mr. Justice Lawrence concurred.

THE INDIAN MEDICAL SERVICE.—There are twenty three appointments to be made in Her Majesty's Indian Medical Service. This being an exceedingly popular branch of the public services, applicants always in excess of vacancies. Notice is given in our advertising columns of the next examination to be held in London on July 28th and following days. Applications for admission must be sent to the Military Secretary, India Office.

PUBLIC HEALTH.—The Parkes Memorial Prize is limited to competition among the Medical Officers of the Royal Navy, Army, and Indian Medical Services of executive rank on full pay, with the exception of the assistant professors of the Army Medical School during their terms of office. during their term of office.

SANITATION IN THE SCHOOLROOM.

SANITATION IN THE SCHOOLROOM.

TEACHER (to applicant for admission): Have you a certificate of vaccination for small-pox? Yes, sir.
Have you been inoculated for croup? Yes, sir.
Been treated with diphtheria serum? Yes, sir.
Had your arm scratched with cholera bacilli? Yes, sir.
Had your arm scratched with cholera bacilli? Yes, sir.
Have you a written guarantee that you are proof against whooping-cough, measles, mumps, scarlet fever, and old age? Yes sir.
Do you promise not to exchange sponges with the boy next to you, and never to use any but your own pencil? Yes, sir.
Will you agree to have your books fumigated with sulphur and sprinkle your clothes with chloride of lime once a week? Yes, sir.
As you have met the requirements of the modern sanitarians, you may climb over yonder rail, occupy an isolated aluminum seat, and begin making P's and Q's as your first lesson.—American Journal of Pracucal Medicine. of Practical Medicine.

M.R.C.S., L.R.C.P.—The matter is under our consideration, and our correspondent will receive a private note in the course of a few

SpES .- Full details will be found in our advertising columns

F.B.C.S.—The election of president takes place at the first meeting of the Council of the College of Surgeons, England, after the annual election of councillors. The procedure is by ballot, each member of the Council voting for whom he feels inclined.

MATRON.-We cannot undertake to advise our correspondent under the circumstances.

Meetings of the Societies and Tectures.

WEDNESDAY, JUNE 14TH.

NORTH-WEST LONDON CLINICAL SOCIETY (North-West London Hospital). - 8.30 p.m. Clinical Meeting.

THURSDAY, JUNE 15TH.

CENTRAL LONDON THROAT, NOSE, AND EAR HOSPITAL (Gray's Inn Road).—5 p.m. Dr. D. Grant: Diagnosis and Treatment of Dangerous Sequelæ of Otitis.

FRIDAY, JUNE 16TH.

WEST LONDON MEDICO-CHIRURGICAL SOCIETY (Town Hall, Hammersmith, W.).—8.30 p.m. Professor W. Osler: Cerebro-Spinal Fever. (Cavendish Lecture).

SATURDAY, JUNE 17TH.

NEUROLOGICAL SOCIETY OF LONDON (Physiological Laboratory, Cambridge).—4.15 p.m. Paper: Dr. W. H. R. Rivers: Some Physiological Observations on the Natives of Torres Straits. 6.30 p.m. Dinner in Trinity Hall.

Bacancies.

Bedford County Hospital.—Senior House Surgeon for one year. Salary, £100, with apartments, board, and washing. Bradford Boyal Infirmary.— Dispensary Surgeon, unmarried. Salary, £100 per annum, with board and residence. Brighton and Hove Dispensary, Brighton.—House Surgeon to the Western Branch, unmarried. Salary, £140 per annum, with furnished apartments, coals, gas, and attendance, but without board.

County and City Asylum, Hereford.—Assistant Medical Officer for ten or twelve weeks. Salary, £2 2s. per week, with board, lodging, &c.—Apply to the Medical Superintendent.

County Asylum, Rainhill, near Liverpool.—Senior Assistant Medical Officer, unmarried. Salary commencing at £225 per annum, with furmshed apartments, board, attendance, and washing.

modes Royal Infirmary. — Resident Medical Assistant for six months. Salary at the rate of £40 per annum, with board and Dundas washing

Fisherton Asylum.—Assistant Medical Officer. Salary commencing

at £120 per annum, with board, lodging, and washing.—Apply to Dr. Finch, The Asylum, Salisbury.

agow Corporation. — Bacteriologist in connection with the Health Department of the City. Salary at the rate of £350 per annum. — Applications to the Clerk (Police Department), Glasgow Cor Health D

Glasgow.

King's Norton Union.—Resident Deputy Medical Officer at the infirmary and the workhouse at Selly Oak, near Birmingham. Salary commencing at £170 per annum, with furnished residence. Bations or attendance not provided. Applications to the Clerk, 10 Newhall Street, Birmingham.

London County Asylum, Claybury, Woodford Bridge, Essex.—Junior Assistant Medical Officer, male. Salary, £150 per annum, with board, furnished apartments, and washing. Applications to the Clerk of the Asylums Committee, 6 Waterloo Place, S.W.

Newport and Monmonthshire Hospital—House Suppose.

ewport and Monmouthshire Hospital.—House Surgeon. Salary, £100 per annum, with board and residence (no stimulants pro-vided).

vided).

Owens College, Manchester.—Senior Demonstrator in Physiology.

Stipend £150 per annum, rising to £200.

Royal United Hospital, Bath.—House Surgeon on July 1st, for three months. Salary at the rate of £60 per annum, with board, lodging and washing.

Staffordshire County Asylum at Stafford.—Medical Officer for two or three months. Salary, three guineas per week, with furnished apartments, board, &c.

West Derby Union.—Resident Assistant Medical Officer at Mill Road Infirmary, Everton. Salary, £100, with rations.—Apply to the Clerk, Brougham Terrace, Liverpool.

Appointments.

ALLRIE, F. W., M.B., C.M.Ed., Medical Officer for the Second Sanitary District of the Ashton-under-Lyne Union.

Black, L. P., M.B., B.C.Camb., L.R.C.P.Lond., M.R.C.S., Medical Officer by the Braintree Rural District Council, pro tem.

BRADSHAW, J. C., L.R.C.P., L.R.C.S.Edin., D.P.H., Medical Officer for the Walton Sanitary District of the West Derby Union.

BROWNE, B. S., L.R.C.P., L.R.C.S.Edin., Medical Officer for the Workhouse and the Alcester Sanitary District of the Alcester Union.

Union.
Coles, C., M.D.Lond., L.R.C.P., M.R.C.S., Medical Officer of Health for the Combined Districts of the town and shire of

Health for the Combined Districts of the town and shire of Leicester.

Fox, H. C., M.R.C.S., L.S.A., Divisional Surgeon of Metropolitan Police for St. Ann's, Stamford Hill.

HAIR, ALLAN, M.R.C.S., L.R.C.P.Lond., Assistant Medical Officer to the North-Western Fever Hospital, Hampstead.

HUGHES, J. BRADLEY, L.R.C.P.Lond., M.R.C.S., Semior Resident Medical Officer to the Toxteth Workhouse Infirmary.

LAW, J., L.R.C.P.Lond., M.R.C.S., Medical Officer for the Sixth Sanitary District of the Township of Oldham, the Oldham Uniton. Union.

Union.

MCRAE G. DOUGLAS, M.B., C.M.Edin, Assistant Physician to the Royal Asylum, Morningside, Edinburgh.

POTTER, S. L., L.R.C.P., L.R.C.S.Edin., L.F.P.S.Glasg., Medical Officer for the Dewsbury Workhouse and Infirmary.

SCOTT, J. B., M.B., C.M.Edin., Medical Officer for the Seventh Sanitary District of the Ashton-under-Lyne Union.

SLOCOCK, R., L.R.C.P.Lond., M.R.C.S., Medical Officer for the Spilsby East Sanitary District of the Spilsby Union.

STEELE, FRANK, M.R.C.S., L.R.C.P., Medical Officer to the Casualty Department, East London Hospital for Children.

STEVENSON, ROLAND A., L.R.C.P.Lond., M.R.C.S.Eng., Second Assistant Medical Officer to the Fulham Road Infirmary, Parish of St. George's, Hanover Square, London.

TAILOR, F. R. P., M.D.Lond., R.S., L.R.C.P., M.R.C.S., Medical Superintendent of the Darenth Asylum, Metropolitan Asylum District.

Births.

EVANS.—On June 7th, at 13 Taviton Street, Gordon Square, London the wife of Wilmot Evans, B.S., F.B.C.S., of a son.
SEMPLE. - On June 9th, at Whitchurch Villa, Sholing, Southampton, the wife of Major G. Semple, M.D., Boyal Army Medical

Corps, of a son.

Marriages.

COOKE-JONES.

DEE-JONES.—On June 6th, at the Welsh Calvinistic Methodist Chapel, Garston, Ebenezer Hunt Cooke, M.A., M.B., of Bhusswal, India, to Katie Williams, only daughter of B. W. Jones, of Garston, Liverpool.

WDSLEY—GARDNER.—On June 8th, at Holy Trinity Church, Ilfracombe, John Herbert St. Hill Mawdsley, of St. Kilda, Taunton, to Elizabeth Mawdsley Gardner, youngest daughter of Frederick Gardner, L.B.C.P., M.B.C.S., of Belmont, Ilfracombe

Beaths.

LEY.—On June 1st, at Ealing, Edwin Granville Ley, M.D., Deputy Surgeon General, late A.M.D.

MOIR.—On June 7th, at St. Andrews, N.B., Bobert Motr, M.D., F.B.C.S.E., Surgeon Major (retired) Indian Medical Service.

POLLEXPEN.—On June 6th, John Hutton Pollexfen, M.A., M.D., for twenty-five years Vicar of Middleton Tyas, Yorks, aged 86.

TOPHAM.—On June 9th, at Wootton Hill, Bournemouth, Herbert Toplam, M.B.C.S., aged 58.

TURNOUR.—On June 8th, at Denbigh, Ed. A. Turnour, Mayor of Denbigh, only son of Arthur E. Turnour, M.D., J.P., of Denbigh, aged 35.

BAYER'S

PHARMACEUTICAL SPECIALITIES.

An ideal astringent in infantile diarrhea, colic enteritis, dysentery, etc. An acetic derivative of tannin without taste or smell. Insoluble in water or dilute acids, but easily soluble in the presence of alkalis.

TANNIGEN

(Triacetyl of Tannin).

An ideal substitute for the Salicy-lates, having no irritating effect on the stomach, through which it passes unchanged, decomposing only in the alkaline intestinal fluid. It is free from the unpleasant after effects so frequently attending the use of Salicylic Acid and its salts.

An excellent substitute for Codeine. In doses of 1-12th of a grain. Heroin has given most excellent results in cases of Bronchitis, Pharyngitis, Catarrh of the Lungs, and in Asthma Bronchiale. In the latter two cases the dose may be increased to 1-6th of a grain.

ASPIRIN

(Acetic Ether of Salicylic Acid.)

HEROIN

(Di-acetic Ether of Morphine).

MAY be prescribed in all cases where it is desired to produce an astringent action on the intestinal mucus. Renders especially valuable service in acute and chronic colic, and is a specific in summer diarrheea of children.

Dose: Children 2 to 5 grains; Adults, 8 to 12 grains 4 or 6 times a day.

It has an agreeable, slightly acid taste, favourably contrasting with the repugnant sweet taste of the Salicylates. Extensive clinical trials have proved the value of Aspirin as a perfect substitute for Salicylic Acid and its salts.

Dose: 16 grains, 3 or 4 times a day.

HEROIN does not cause constipation, and may be administered to patients with a weak heart who cannot tolerate Morphine.

Hydrochloride of Heroin. A neutral Heroin salt, easily soluble in water, and suitable for subcutaneous injection.

Dose, subcutaneously, 1-20th to 1-6th of a grain.

Trional, Tannigen, Salophen, Lycetol, Creosotal, Duotal, Heroin, Aristol, Tetronal, Analgen, Losophan, Somatose, Iron Somatose, Milk Somatose, Phenacetine-Bayer, Sulfonal-Bayer, Piperazine-Bayer, Salol-Bayer.

Samples and Literature may be had on application to the Wholesale Depot for all Bayer's Pharmaceutical Specialities.

THE BAYER CO., Ltd., 19 ST. DUNSTAN'S HILL, LONDON, E.C.

Also at MANCHESTER, GLASGOW, and BRADFORD.

REPORT

On an Exact Bacteriological Investigation made to ascertain the Value of " Oil, & "Sanitas" Emulsion

As DISINFECTANTS for GENERAL USE,

By C. G. MOOR, M.A. (Cantab.), F.I.C., F.C.S.,

Member of the Society of Public Analysts, Joint Author of "Applied Bacteriology," &c., &c.

4 DANES INN, W.C., LONDON, July 2nd, 1898.

C. T. KINGZETT, Esq., F.I.C., F.C.S.,

THE "SANITAS" COMPANY, LIMITED,

BETHNAL GREEN, LONDON, E.

BETHNAL GREEN, LONDON, E.

DEAR SIR,

I beg to present you my report on the experimental investigations I have conducted on the preparations manufactured by your firm, named "Sanitas" Oil, "Sanitas" Emulsion, and "Sanitas" Fluid.

The experiments were made to ascertain and establish, if possible, on a scientific basis, the efficiency of these preparations, and their suitability for the purposes for which they are designed as indicated by your publications and labels giving directions for use.

The experiments instituted for this purpose were as follows:

(a) In the case of the preparations above mentioned, various disease organisms—namely, those of Anthrax, Cholera, Diphtheria, Staphylococcus Pyogenes Aureus and Typhoid were brought into contact with the disinfectant for a given time and in a manner detailed below, and means were taken to ascertain whether the disinfectant employed was sufficiently powerful to determine the death of the organism in a given time.

(b) A second series of experiments was undertaken to ascertain the effect when similar cultures were exposed to different strengths of these disinfectants for a standard time.

(c) Experiments were also made to ascertain the effect on ordinary air, as regards the removal or extermination of organisms suspended in it, by spraying with "Sanitas" Oil and "Sanitas" Oil and experimented as to the action of the yanour given off at a temperature not exceeding the content of the action of the yanour given off at a temperature not exceeding the content of the content of the content of the action of the yanour given off at a temperature not exceeding the content of the content of the action of the yanour given off at a temperature not exceeding the content of the content of the action of the yanour given off at a temperature not exceeding the content of the content of the action of the yanour given off at a temperature not exceeding the content of the content of the content of the action of the yanour given off at a temperature not exceeding the content of the c

"Sanitas" Fluid.
(b) In the case of "Sanitas" Oil, I have experimented as to the action of the vapour given off at a temperature not exceeding that of the human body.
(e) Finally, I have tried some experiments to ascertain the action of "Sanitas" Oil and "Sanitas" Fluid on the Bacillus of

Plague

TABLE 1.

EXPERIMENTS WITH "SANITAS" OIL.

Silk threads infected with cultures of the following organisms were exposed in "SANITAS" OIL for the times shown below and then incubated in broth. Growth is shown by a + sign, no growth by a - sign.

Diphtheria				 	i — .	_	_	
S. P. Aureus	١			 	+	_	-	
Typhoid				 	-	_		

Controls all grew well.

Controls all grew well.

I next proceeded to ascertain the strengths of these disinfectants required to ensure the death of the above-named bacteria in a given time—and in the following experiments the time of exposure of the bacteria to the action of the disinfectant was in all cases ten minutes. In these experiments 1 used the method of shaking together an actively growing broth culture of the organism to be tested, with such a qu ntity of disinfectant that the resulting mixture contained the strength of disinfectant specified in the tables below; the exact details of the method of experiment are described in Pearmain & Moor's Applied Bacteriology, 2nd Edition, pages 377-382. (Ballière, Tindall, and Cox).

TABLE 3.

"SANITAS OIL.—As the Oil is not readily miscible with water e "Sanitas" Emulsion, which contains 45 per cent. of "Sanitas" Oil, was employed.

Ten minutes' exposure.

	no.	IN 16.	A .S.		50 °/。	25 °/°	10 %	
Cholera				 	_	_		
Diphtheria				 	_	_	-	
Typhoid				 	_	-	_	

Anthrax and S. P. Aureus were also both destroyed by the 50 % mixture in ten minuces' exposure. Controls all grew well

(6). I have made several experiments as to the destruction of bacteria floating in the air of a room by spraying the air with "Sanitas" Oil, and with "Sanitas" Fluid—testing the air by means of Hesse's tube.

The removal of bacteria from air by spraying will, doubtless, depend very greatly on the mechanical action of the particles of spray, because, as is well known, bacteria are very largely removed from air by a shower of rain, therefore, too much importance must not be attached

ashower of rain, therefore, too much importance must not be attached to such experiments.

Taking, however, the mean of several experiments, whereas the air of the room contained a considerable number of bacteria before spraying, the numbers were reduced, after spraying, to under five per cent. of those previously found.

(8). "Sanitas" Fluid does not give off much vapour at ordinary temperatures; but, Sanitas" Oil, on the other hand, is sensibly volatile at room temperature, and I have tested the action of the vapour given off by "Sanitas" Oil, at blood-heat on bacteria similar to those used in the broth and thread experiments.

Some of the growth from agar tubes was smeared on filter-paper and suspended in a wide-mouthed jar containing a little "Sanitas" Oil. The whole was placed in the incubator (37° C.), and, after an hour, cultures were made on to nutrient media. The result was that only the two most resistant organisms—namely, Anthrax and Staphyloloccus Pyogenes aureus - had survived, while Cholera, Diphtheria, and Typhoid falled to grow Typhoid failed to grow

(7). Having a culture of Bubonic Plague brought by a student from Hong-Kong I tried the effect of "Sanitas" Fluid and "Sanitas" Oil on it. The bacillus was killed in each case by a ten minutes exposure to a strength of 33 per cent. of each disinfectant—the only strength

tested.

In conclusion, I regard the results of my investigation as affording ample evidence that the "Sanitas" preparations are thoroughly reliable, when employed in the strengths and for the purposes specified in the directions issued by the proprietors, while their non-poisonous nature and pleasant character render them applicable in many instances where such substances as carbolic acid or mercurial chloride would be inadmissible or dangerous.

The Cavendish Lecture

ON THE

ETIOLOGY AND DIAGNOSIS OF CEREBRO-SPINAL FEVER. (a)

By WILLIAM OSLER, M.D., F.R.S., F.R.C.P., Professor of Clinical Medicine, Johns Hopkins University, Baltimore, U.S.A.

In practice we sometimes meet with a meningitis which is not a sequel to pneumonia or ulcerative endocarditis, to ear disease or of injury, and which does not mark the terminal stage of a chronic malady. As the meninges of brain and cord are both inflamed the condition is labelled cerebro-spinal meningitis. When there are many cases we speak of epidemic cerebro spinal meningitis. Until recently my experience did not extend beyond the sporadic form of the disease. However, the recurrence of a small outbreak in Baltimore during the past year has enabled me to study certain points in this most interesting affection, and has thus determined my choice of a subject upon which to address you.

Of the special features of epidemic cerebro-spinal

fever I shall speak but briefly.

First, it is one of the most fatal of all acute diseases, but fortunately takes a low position among destructive epidemics. It spreads slowly and attacks only a few individuals so that the general mortality may be but slightly increased. On the other hand, scarcely any known fever kills so large a proportion of those attacked. During the recent Boston epidemic out of 111 hospital cases no less than 76 died.

Secondly, the outbreaks occur in epidemic waves, of which the fourth in the present century is now prevailing in the United States. For some years there have been local outbreaks in widely-separated regions, but in 1896, 1897, and 1898 a slight epidemic occurred in Boston, and in 1898 cases appeared in Baltimore and other towns. From a recent report by Surgeon General Wyman we find that cerebro-spinal fever has prevailed during the past year in twenty-seven States.

prevailed during the past year in twenty-seven States. Thirdly, among specific diseases cerebro-spinal fever comes closest to pneumonia. Sporadic cases of both occur during epidemic periods, although more commonly so in pneumonia, while both are most frequent in barracks, gaols, and asylums. Even when not epidemic there may be remarkable house outbreaks of cerebro-spinal fever. The seasonal relations are the same in both, and the two diseases may prevail together. Other points of resemblance are found in the abrupt onset, the herpes, the almost identical character of the fibrino-purulent exudate, as pointed out by Netter, and the frequent complication of pneumonia by meningitis, and of the latter by pneumonia. The degree of contagion is about the same in both diseases, and it has been claimed that the organism described in cerebro-spinal fever is only a degenerate variety of the pneumococcus.

a degenerate variety of the pneumococcus.

On the other hand, Leichtensten urges against the view that pneumococcus is the cause of epidemic cerebro-spinal meningitis the facts that pneumonia is of universal distribution, whereas the other condi-

tion is very rare, and in some countries still unknown. Croupous pneumonia attacks every age, and somewhat more so with increasing age, while epidemic meningitis chiefly affects children and young persons. Pneumonia has a typical course and crisis: epidemic meningitis has no crisis. The complications also differ.

THE BACTERIOLOGY OF CEREBRO-SPINAL FEVER. More than twelve years ago Weichelsbaum described a diplococcus with special cultural peculiarities, which he claimed to be the specific organism of the disease. In 1895 his observation was confirmed by Jaeger. No mention, however, was made of the fact in Allbut's System, published in 1896, or in Lowne's and Thompson's System in 1897. Weichelsbaum has and Thompson's System in 1897. Weichelsbaum has been confirmed by Heubner, Councilman, Mallory, and Wright, and the organism, known as the meningo - coccus, or the diplococcus intracellularis meningites, is now regarded as the specific cause of the malady. The subject is fully discussed by Netter in Vol. XVI. of the "Twentieth Century Practice" My own cases have been carefully investigated by my colleagues, Drs. Gwyn, Harris, and Welch. The meningococcus in coversiling from the exudate is usually a diplococcus lying slips from the exudate is usually a diplococcus lying within the polynuclear leucocytes; hence the term intracellularis. It may also occur free. It is stained with the ordinary reagents, and is decoloured by Gram's method. It grows best on Loeffler's blood serum, on which it forms round, whitish, shining. viscid-looking colonies, with smooth, sharply-defined outlines, which contain a diameter of 1 to 1; millimetres in twenty-four hours. It is found in the cerebro-spinal exudates, and has been rarely isolated from the blood, pus from joints, pneumonic areas in the lungs, and nasal mucus.

Our clinical and pathological experience with the organism is as follows:—In twenty-one cases which I have seen lumbar puncture was made in sixteen. In three cases seen in consultation the diagnosis was so clear that puncture was not made. In Cases 1 and 2, both mild, the puncture was made, one on the sixth and the other on the seventh day, but no organisms were found, In Cases 3 and 4, admitted late in the disease, it was not thought necessary to Of the remaining fourteen cases, in perform it. thirteen the diplococcus intracellularis was present on coverslips and in cultures. In the fourteenth case its presence was doubtful on the coverslips, but the staphylococcus was found in culture. Of the five autopsies the diplococcus intracellularis was present, and in two had been found during life. In one the streptococcus and in another the staphylococcus was isolated.

MICROBIC ASSOCIATION IN CEREBRO-SPINAL FEVER.

It is interesting to note that the diplococcus intracellularis is often found to be not in pure culture. In the Boston epidemic other organisms were often found, particularly in lumbar punctures taken in the course of the disease. In a large number of Netter's cases the pneumococcus was present. In our own series it was found only once in the fluid obtained by lumbar puncture. Another point in diagnosis is that after five or six weeks or longer the diplococcus

⁽a) Read before the West London Medico-Chirurgical Society, June 18th, 1899.

intracellularis often disappears. The chief organisms found in association are the pyogenic organisms, the pneumococcus, and rarely, the tubercle bacillus.

On the whole, then, our observations support those of Weichelsbaum, Jaeger, Councilman, and others, that in epidemic cerebro-spinal fever there is an organism with special cultured peculiarities which may reasonably be regarded as the exciting cause of the disease. Among recent observers, Netter alone appears to doubt this, and says that he found the diplococcus intracellularis in 16 only out of 39 cases. and in 10 of those the pneumococcus was present at the same time.

Netter's position is illogical and confusing. In his article in the "Twentieth Century Practice" he assumes that cerebro-spinal fever may be caused by either the pneumococcus or the diplococcus intra-cellularis. That a cerebro-spinal meningitis may be due to the pneumococcus is everywhere acknowledged; but it is unlikely that so specific an affection as cerebic spinal fever should be caused by two different organisms. Towards the close of the article the inconsistency of this view seems to impress him, for he says, "certain peculiarities prevent us from con-cluding that the two diseases are absolutely identical."

THE DIAGNOSIS.

In cerebro-spinal fever the disclosures of the post-mortem room are just as mortifying as in pericarditis. Who has not in enteric fever or pneumonia made an absolute diagnosis of meningitis, only to illustrate the dictum of Stokes that there is no single nerve symptom which does not and may not occur independently of any lesion of brain, nerve, or spinal cord? It is very doubtful if either tubercu-lous or pyogenic organisms cause an acute primary

cerebro-spinal lepto-meningitis. The onset of the disease is peculiar. As a rule it is more abrupt than that of any other known disease, with the possible exception of pneumonia. The patient may be seized when at work or during sleep, he has rigors or chill. This onset is very different from that of the tuberculous form. In sporadic cases of cerebro-spinal attacks there may be no fever at first. (Various charts illustrating the peculiarities of temperature were here shown on a lantern screen.) In two cases there was no elevation of temperature for three or four days, then the curve ran up suddenly to 104 degs. or 105 degs Another chart showed extreme fluctuations from about normal to 106 degs. and 108 degs. (the latter preceding death). In another less common type the fever was continuous, resembling the third week or recovery stage of enteric fever. In one case regarded as typhoid the diagnosis of cerebro-spinal fever was established by lumbar puncture. One protracted case showed extreme irregularity, and at one time an inverse type of temperature—that is to say, a morning record higher than that of the evening. In some the fever is of a remarkably intermittent nature. It differs, however, from the paroxysms of intermittent fever in extending over twenty-four hours, whereas the intermittent periodicity occurs every twelve hours.

KERNIG'S SIGN.

This interesting sign, first described by a Russian physician, has been present in all of our cases in which it has been looked for. It is an old observation that in protracted meningitis the patients lie with the thighs flexed upon the abdomen and the legs partly flexed on the thighs. To test for Kernig's sign the patient should be propped up in bed in the sitting position, then, on attempting to extend the leg on the thigh there is contraction of the flexors which prevents the full straightening of the leg. On the other hand, in the recumbent posture the leg can be fully extended. Many patients with meningitis

cannot sit up, but the test can be equally well applied by flexing the thigh on the abdomen, when, on attempting to extend the leg, if meningitis be present. the limb cannot be fully extended. Frics found the sign in fifty-three out of sixty cases, and Netter in forty-five out of fifty. Its presence is no indication of the intensity of the spinal involvement. Netter's explanation of the phenomenon is as follows: In consequence of the inflammation of the meninges the roots of the nerves become irritable, and the flexion of the thighs upon the pelvis when the patient is in the sitting posture elongates, and consequently stretches the lumbar and sacral roots, and thus increases their irritability. The attempt to extend the knee is insufficient to provoke a reflex contraction of the flexors while the patient lies on his back with the thighs extended upon the pelvis, but it does so when he assumes a sitting posture."

LUMBAR PUNCTURE.

By means of Quincke's lumbar puncture we can now say when a meningitis exists and are further able to determine the form of the disease. technique of the operation is fully described in the text-books. It is a simple, harmless procedure, and in most cases can be undertaken without general ansesthesia, or with the aid of a local freezing mixture. The puncture is usually made between the second and third lumber vertebree, and is done with an ordinary aspirating needle. Often a few drops of blood flow first, then a clear or turbid fluid. A dry tap is unusual in cerebro-spinal fever. The needle may be plugged, or may be in contact with a nerve. In rare cases clear fluid may be obtained when meningitis exists, and in a protracted case the fluid may be turbid at one puncture and clear at the next. A clear fluid may be obtained from a puncture in the second lumbar interspace, while lower down a turbid fluid may be withdrawn. In a recent post-mortem the fluid in the dorsal and upper lumbar regions was clear, while that in the lower lumbar and the sacral canal was turbid and flocculent. The amount of fluid varies from a few drops to a large amount—e.g. 126 c.c. Cover glass preparations can be made at once, and cultures prepared by running a few cubic centimetres of the fluid on to a shunt tube of Loeffler's blood serum.

Has the lumbar puncture any therapeutic value? Williams, of Boston. thought it had, but Wentworth takes a contrary view. Netter reports some good results. We have given this point careful attention. In one chronic case the patient lingered three months. Seventeen punctures were made in all between the twenty-ninth and the seventy-fifth days of the disease, and of these fourteen were positive. A turbid, pale yellow fluid was removed at each effective tapping. On five occasions 100 cc. or more were obtained, once 125 cc., and once 126 cc. After the first two effective tappings the patient seemed better, the ten punctures dropped and he seemed much brighter, but he soon became worse, and the fever rose. Following the sixth, seventh, eighth and eleventh punctures the temperature fell 4.5 degs., 3.8 degs., 4.2 degs., and 5.8 degs. The drop in the fever followed so directly that it seemed only natural to attribute it to the lumbar puncture. The thirteenth puncture, however, was negative, yet the temperature fell 5.1 degs., and after the fourteenth tapping the temperature rose 2.6 degs. Evidently not the withdrawal of the fluid, but the peculiar character of the disease was responsible for the remission. The diplococcus intracellularis was found twice.

SPORADIC CEREBRO-SPINAL FEVER.

To what extent do isolated cases of cerebro-spinal fever occur between the epidemics? What is the nature of the primary suppurative meningitis which is met with from time to time in all communities

Neither hospital statistics nor the ordinary death returns give any trustworthy information as to these questions,

From the Fifty-ninth Annual Report of the Registrar-General, 1896, I gather that the deaths from cerebro-spinal fever in England from 1877 to 1896 inclusive, have only once exceeded 50 per annum. There has been a great reduction in the return since 1887, 233 cases for the ten years ending 1896, against 406 for the previous decade. In Scotland there were only six deaths from cerebro-spinal fever in 1895, and five in 1896. In Ireland there were 76 deaths from this cause in 1896, and the same number in 1897.

In the United States and Canada the occurrence of sporadic cases in the intervals between the epidemics has long been recognised. In Philadelphia, from 1863 up to the present date, a record has been made by Stillé, Pepper, and Abbott. They show a gradual decline from 1884, when there were 124 deaths, to 1891, with 23 deaths. From 1892 to 1897, the deaths were 22, 35, 18, 17, 7, 10; 1898, 24 cases; while in the first four months of the present were while in the first four months of the present year there were no less than 89 deaths.

At the Johns Hopkins Hospital in the Spring of 1898 there were four cases of sporadic cerebro-spinal

fever; the first of the epidemic cases.

One family presented the following history:—(1) a son, a young man, set. 20, returned home with a terrible pain in the head. He had fever and vomiting and his head and neck were arched. He was delirious and died in five days; (2) a sister who nursed her brother, died in four days; (3) a second sister taken ill and recovered; (4) the mother, worn out with nursing her children, attacked and died in two days. These were five cases of the sporadic form in one family. The disease was not epidemic in the city.

BACTERIOLOGY OF SPORADIC CEREBRO-SPINAL

In a number of sporadic cases the organism of Weichelsbaum has been found. The most important contribution of late years has been made by Dr. Hill, of the Great Ormond Street Hospital for Children. In a study of the simple posterior basic meningitis of infants he isolated from seven or eight cases a diplococcus conforming in every respect with the diplococcus intracellularis. In ten years there were forty-nine fatal cases of the kind at the hospital mentioned. Clinically the disease differs from the ordinary type, as it attacks young children and is very protracted. Skin rashes are not frequent. Still was able to isolate the diplococcus from the periarthritic exudates.

By the kindness of Professor Welch the results of the twenty-five cases in our own city in which bacteriological examination has been made may be here given. There were six of cerebro-spinal fever, eight of pneumococcic meningitis, seven of pyogenic meningitis (in which streptococci and staphylococci were found together and separately), and four show-

ing unidentified bacilli.

The pyogenic forms of meningitis do not concern us here; no case of primary streptococcus or staphylococcus came to autopsy. I have already referred to the chronic form of cerebro-spinal fever in which the pyogenic cocci may alone be present at the time of death.

PNEUMOCOCCIC MENINGITIS.

The pneumococcus has long been recognised as the most important organism in the production of meningitis, and the first question is how far sporadic cases of cerebro-spinal meningitis are due to it. Of twentyfive cases in the Johns Hopkins Hospital it was isolated in eight. Of twenty cases examined by Councilman, Mallory, and Wright, it was primary in wo and secondary in eight. Netter examined sixty-

one cases of meningitis bacteriologically, and found the pneumococcus thirty-five times, the same with streptococcus once, and once with staphylococcus, the streptococcus alone thirteen times, the diplococcus intracellularis three times. We may consider three groups of pneumococcic meningitis.

1. The meningitis as a complication of lobar pneumonia. In Montreal my attention was called to the frequency of this complication in eight of one hundred consecutive autopsies. The other groups are pneumococcic meningitis from local infection, and

primary pneumococcic meningitis.

The clinical features of pneumococcic meningitis present many points of interest. Is the case one of cerebro-spinal fever with pneumonia, or of inflammation of the lungs, with an added meningitis? This question does not often arise at the bedside, as it is most exceptional for the meningitis of pneumonia to present the symptoms of cerebro-spinal fever, and in doubtful cases the lumbar puncture will settle the matter. The age of the patient is important. In meningitis complicating pneumonia all the cases were above the twentieth year, a striking contrast to cerebro-spinal fever, in which a large proportion are under twenty. A second point is the latency of pneumonia, which is much more often recognised in the deadhouse than in the wards. Netter states that fully one-half of the cases are latent. Headache and early delirium are present in all cases, owing to involvement of cortex. On the other hand, the mind may remain clear throughout cerebro-spinal fever. Spinal symptoms are rare in the meningitis of pneumonia. The importance of lumbar puncture cannot be too strongly emphasised. In a case of pneumonia in the wards of cerebral symptoms, the puncture showed the pneumococcus in the exudate. Lastly, an important point is that meningitis complicating pneumonia is almost always fatal. Personally I have never seen recovery under these conditions.

Secondary meningitis from local infection from nose, ear, &c., is often of pneumococcic origin.

Primary pneumococcic meningitis exists, and is abrupt in onset. The most important point to be determined is the exact proportion of primary cerebro-spinal meningitis due to pueumococcus and to diplococcus intracellularis.

TREATMENT.

In our cases no special drugs were used. Morphia was given to check pain, and sponging practised to reduced temperature. Our mortality has not been very great when we consider the severity of the cases, thus eight cases died out of eighteen in hospital, and nine among the twenty one I have seen. A distinguishing feature is the relief of pressure by withdrawal of cerebro-spinal fluid.

In two of our cases the spinal canal has been opened, drained, and irrigated. So far as I know, an extensive laminectomy had not been done for acute spinal meningitis until our first case on November 6th, 1898, was operated upon by Dr. Cushing. The spinal canal was thoroughly irrigated with salt solution and a quantity of purulent exudate washed out. No change followed in the existing paraplegia. The bladder and kidneys became infected, and the patient died two months after the operation. At the autopsy spinal meninges were smooth and looked normal. It was impossible to say where the dura mater had been incised, and there were neither adhesions nor thickening of the pia-arachnoid.

In another case laminectomy was performed on the fourth day by Dr. Cushing. A catheter was passed beneath the dura mater, and the membranes drained and irrigated. For several days the patient seemed better, but he developed a hæmorrhagic cystitis, and died on the sixth day after operation.

Dr. Musser, of Philadelphia, has also had an un-

Digitized by GOOGLE

successful case. In England Dr. Rodleston, and Mr. Herbert Allingham have reported a case of sporadic cerebro-spinal meningitis, in which the patient recovered after laminectomy and drainage. The operation, which has been adversely criticised in some quarters, seems to me justifiable in severe cases, where the spinal symptoms are very marked, on the principle of a desperate remedy for a desperate disease.

THE ERADICATION ()F TUBER-CULOSIS.

By GEORGE FLEMING, C.B., F.R.C.V.S., LL.D., Late Principal Veterinary Surgeon to Her Majesty's Forces.

THE intense interest that is now being taken by the public in the subject of tuberculosis is, it is to be hoped, an indication that at length active measures will be speedily inaugurated to diminish its preva-lence in man and beast, and ultimately lead to its total suppression. For of all the diseases with which we are acquainted this is certainly the most prevalent, as it is by far the most destructive. It is estimated that it destroys, in its various forms, one-seventh of mankind, and its ravages are experienced more or less in every part of the world. Its pernicious influence on human existence may be estimated, when we consider that in Great Britain it is account-able for nearly half the number of deaths occurring between the marriageable ages of 15 and 35 years, and causes one-fifth of the entire mortality. What loss it may occasion during the earlier years of life is difficult to ascertain, as perhaps more than one disease is included under this designation; but there can be no doubt that the death rate from tuberculosis among children under two years of age is very great. The total annual mortality in this country from this scourge alone, has been set down at 70,000; but it may be greater, for the reason just stated, as the disease appears in various forms, which, receiving different names, are liable to mislead as to their real nature

Surely this must be looked upon as a most serious affliction, and one which demands every possible effort to be made for its removal! And that its mitigation and eventual eradication are possible, there can be no reason whatever to doubt; it only requires the devising of proper sanitary measures, and the patient and careful enforcement of these, to ensure the attainment of this most desirable object. But it would appear that these measures will not be instituted unless the public press for them, and when inaugurated they cannot be carried into successful operation unless the public heartily and energetically support them. The sanitary measures to be adopted must be based on the fact that tuberculosis is an infectious disease, and that it owes its maintenance and extension to its infectiousness alone. It is a disease due to a specific germ, a bacillus, and without this germ there can be no tuberculosis, phthisis, consumption, or whatever other names may be applied to the different forms the malady assumes.

Had this fact been earlier understood, in all probability the ravages of tuberculosis would long ago have been greatly lessened, and we should not now be deploring the sad and astounding mortality it occasions. It is indeed, astonishing, that this very important feature of the disease, its communicability from diseased to healthy people, should have been so long overlooked or only now and again suspected. The immortal Harvey, more than two hundred years ago, was of the opinion that phthisis is a communicable or infectious disorder, and considered that it acted like plague, leprosy, and lues venerea,

"creeping through the ranks of mortal men, and by mere extrinsic contact exciting disease similar to itself in other bodies" And the great anatomist, Morgagni, not long afterwards suggested the infectiousness of phthisis. But it is only within a few years that its infectiousness has been at all generally recognised, and even now there are some persons who remain incredulous, and deny that tuberculosis and leprosy are transmissible from diseased to healthy subjects

subjects. Not being recognised as an infectious disease, attention has until lately been directed entirely to its cure, with what success the figures just referred to will show. Though a small percentage of affected persons recover, yet it must be pronounced a very fatal disorder, and one for which medical treatment can do little in the way of cure. It is not so with preventive or prophylactic measures, to which, if wisely devised and thoroughly carried out, it must eventually yield. But the framing of these measures and the manner in which they are to be brought into operation, must be based on our knowledge of the virulent principle on which its existence depends, the source or sources from which that principle is derived, and the mode in which it is communicated from diseased to healthy people. Tuberculosis is not a disease affecting only mankind; if we were so limited its suppression would be easier, and its diffusion not so subtle and evasive. It is very probable that all warm-blooded creatures are more or less susceptible to its invasion, and that those with which man has the most intimate relations - those which provide him with a considerable portion of his daily food—are largely infected with it. More especially is this the case with bovine animals, in which tuberculosis generally appears in a chronic form, and causes so little disturbance to health in many cases that cattle intensely affected may outwardly appear in good health and fair condition. This is very different to what is witnessed in man, and places bovine tuberculosis in a very serious light, as we shall see presently. And yet it is a destructive disorder, and is estimated to kill forty thousand cattle annually. It has been calculated that from 25 to 40 per cent. of the cows in London are tuberculous, and in Edinburgh, Yorkshire, and Durham from 19 to 23 per cent. Not long ago, when bovine contagious pleuro-pneumonia was being stamped out by slaughter, it was noted that from 20 to 30 per cent. of the cattle destroyed were tubercu-lous. On the European Continent its prevalence varies somewhat. In Germany, some years ago, it was supposed that from 2 to 8 per cent. of all the cattle were affected, but more recent investigations have given rise to the belief that it is quite as high as in this country. In the Leipsic abbatoir, for instance, in 1890, as many as 22 per cent. of all the slaughtered cattle were tuberculous; in 1892, 27 per cent; and in 1894, $29\frac{1}{2}$ per cent. And similar proportions have been remarked in the abbatoirs of other cities. The disease appears to be on the increase nearly all over the world, and it is now the most widespread of all bovine disorders, though it must be ob-served that there are some regions where it is little if at all known. Is is said that Japanese cattle are exempt from it, and in the North of Sweden and Norway, North Africa, the Steppes of Russia, and in Iceland and Sicily, it seldom if ever occurs. Certain breeds are more predisposed to it than others, especially those reared on plains, and it is rare among hill-bred and wild cattle. It is far more common among cattle in towns than among those in the open air of the country, and cows suffer most severely when compared with bulls, oxen, or calves, while old animals are much more frequently

unclean, badly ventilated and lighted, and the drain-

involved than young ones

Where cowsheds are

age is defective, there the disease revels if it once

obtains a footing.

It is probable that bovine tuberculosis was known at a very early period to the Jews and others, and that the flesh of animals affected with it was for-bidden by law to be sold as human food. This was more particularly the case in the fourteenth, fifteenth, and sixteenth centuries, though it does not appear that it was so much from dread of infection as because it was supposed to have some relation to human syphilis, and like that malady, it was named the French disease. Towards the end of the eighteenth century, however, this relationship was denied, and the flesh of tuberculous cattle was pronounced fit for food in Germany and Austria. In the beginning of this century the danger of such flesh was suspected, and in 1816 an authority graded it in three classes: 1. That from which the tuberculous masses were to be removed; (2) that from which the diseased portions were to be excised and destroyed, and the remainder sold at a low price; and (3) that which was quite unfit for

But the transmissibility of the disease from one cow to another does not appear to have been apprehended, and though it was a common affection among dairy cows and caused heavy loss, no precautions were adopted to check it, nor does inquiry seem to have been made as to its nature; and the great majority of writers were of opinion that it was quite different from human tuberculosis. More than forty years ago I had satisfied myself that it could be communicated from an affected to a healthy cow, and evidence of such infection was not far to seek in town dairies. But until experimental research was adopted little of a positive nature was known. In 1865 Villemin began these experimental investigations which yielded such startling results, and clearly demonstrated not only that human and bovine tuberculosis were one and the same disease, but also that the former could be readily transferred to various species of animals by inoculating them or feeding them with tuberculous matter; he was, therefore, the first to prove that it is a specific infective malady, identical in man and cattle. This discovery by Villemin has been strangely lost sight of in this country, the credit for it having been given to Koch; it was quickly verified and established by the experiments of Klebs, Gerlach, Chauveau, St. Cyr, Toussaint, and many others. The results were so remarkable, and gave the bovine disease such a serious aspect, so far as the public health was con-cerned, that I drew attention to the subject in a medical magazine, (a) insisting on the danger attending the consumption of the flesh and milk of diseased animals, and pointing out that much of the mortality among young children might be due to the latter! And the following year, in a work published with a view to the eradication of contagious diseases among animals (b) a section was devoted to the subject of bovine tuberculosis, in which the following passage occurs with reference to milk: "The commencement of phthisis is generally so insiduous in the human species, that it is most difficult to arrive with any degree of certainty at the causes which directly produce or favour its development; but from the evidence before us, it is to be feared that at least one of its sources may be referred to the milk from tuberculous cattle. It is certain that tuberculosis is a somewhat common and a very destructive disease, among dairy cattle especially, and more particularly among those in towns; that the udder is one of the glands not infrequently

involved; that infants and adults consume milk in large quantities-indeed, it is the staple diet of young children; and that phthisis is a very prevalent and fatal malady in the human species, and chiefly among the dwellers in towns and cities. There is every reason, then, to prohibit the use of milk from cows affected with tuberculosis, and especially for infants, who mainly rely upon this fluid for their sustenance, and whose powers of absorption are very active. Even if it did not possess infective properties, its deficiency in nitrogenous elements and fat and sugar, and the increased proportion of mineral matters, would alone render it an objectionable article of diet. It had long been known that it was liable to produce diarrhœa and debility in infants, but though these died from general or localised tuberculosis, the part played by the milk in its production was not suspected."

I believe this reference, and that in the medical journal already mentioned, is the first intimation, in this country at least, of the danger of infection through milk when taken as food, and that this may be one of the sources of human tuberculosis. With regard to the communicability of the disease among cattle, I had also insisted on this in the work just quoted from. "There appear to be many facts to support the popular notion, that the cohabitation of healthy with phthisical cattle will produce the malady in them; the expectorated matters of the diseased being probably the active agent in this contamination. . . there is evidence which appears to prove, in the most conclusive manner, that not only is the disease commmunicable by cohabitation of healthy with diseased cattle, but that stalls and stables may become so contaminated by animals suffering from tuberculosis that they will infect sound cattle which afterwards inhabit them. . . forage soiled by the expectorations of the diseased and consumed by healthy animals will communicate the malady.

So deeply impressed was I with the dangers to the public health to be apprehended from the existence of this disorder in cattle, as well as with its destructiveness among them, that in 1876 I read a paper before the Society of Arts dealing with this subject (a), and soon afterwards, at the annual meeting of the British Medical Association held at Cambridge, I again brought it under notice. In 1880 I published a pamphlet on it, bringing together all the evidence I could collect, in order to direct public attention to it (b), and in 1883 I issued another pam-

phlet containing further evidence (c).

But these efforts to attract attention to this serious matter—serious even because of its increasing prevalence and destructiveness among our cattle-met with little response, and it was not until Koch, in 1882, discovered the micro-organism or bacillus which is the real genetic influence in the production of tuberculosis, that the dangerous character of the disease began to dawn upon the public mind. But this discovery, important though it was, did not in any way prove that the malady was infectious, for experimental and clinical observation had done this years before, and to Villemin are we in-debted for establishing the fact of the communicability of consumption and its identity in man and animals. Even after the discovery of the microorganism very little advance was made towards the prevention of the disease; its cure was the chief object of research, and when, in 1890, Koch introduced a glycerine extract of pure cultivation of the bacilli, it was as a curative agent for phthisis.

quickly found that this "tuberculin," as it was named, was not a cure, and frequently did more harm than confer benefit when inoculated into phthisical people. Its particular action upon cattle, however, was soon observed; for when inoculated into a tuberculous cow, it in a few hours increased the bodily temperature to a marked degree, even when the animal did not offer any external indications of disease. So trustworthy and valuable was this fluid found to be as a diagnostic agent in cattle, when employed with the necessary care and discrimination, that it is now largely resorted to as a test in those occult cases where the ordinary means of investigation would only yield negative results.

(To b: concluded in our nex!.)

THREE CASES OF TACHY-CARDIA. (a).

By J. MAGEE FINNY, M.D., F.R.C.P.I, Physician and Lecturer on Clinical Medicine at Sir Patrick Dun's Hospital, &c.

I AM enabled to bring to your notice the clinical notes of three cases of tachycardia, the first two cases being examples of paroxysmal heart hurry; the third case was persistent for sixteen days, and ended fatally with gangrene of both lower extremities due to arterial thrombosis.

Case 1. was an elderly lady with chronic valvular and arterial disease, who had two attacks of paroxysmal tachycardia while under his care in 1887. The pulse suddenly, with little or no cause, would rise to 160 from 76, and remained at that rate for some hours (4-6), and then the heart recovered its wented rate. The patient made very little of these attacks, and complained of but slight oppression in the chest.

This patient died three years subsequently "of her heart," when not under my care.

Case II. was a lady, et. 52, at the "period of change of life," who had been under medical observation for six months in 1897, and whose heart was frequently examined and found free of valvular and other disease. Suddenly, and apparently without any cause, at 10 p.m., the pulse beat up to 200-240. The patient complained of an oppressed feeling under the sternum, and sat up in bed, propped up. She was manifestly in a state of great fear, but presented no sign of pulmonary distress, the breathing being quiet, the face free from cyanosis, and the extremities being warm. On being reassured she improved, and the attack passed away, after the administration of carminatives and valerian, in about three hours. A second and third attack happened within the next three months, and as she was no longer afraid of them, she sat through them, and then would say, "now it is gone," and the pulse, taken by a medical friend, would have suddenly fallen from 160-180 to 70. For thirteen months this lady travelled abroad without any recurrence, and at Nice learned to ride the bicycle. Since her return to Dublin at the end of 1898 she has had a few recurrences. Those she attributes to mental worry connected with her servants, but when seen in February, 1899, she was well, and her heart and blood vessels were healthy, and she was taking to bicycling again.

Case III. was a previously healthy servant, set. 23, who was sent to Sir Patrick Dun's Hospital by Dr. Bradshaw on June 17th, 1898, with the history of an acute attack of inflammation of the throat, high fever, 104 degs., and pulse 140 of four days' duration. This may have been influenza, as there was neither scarlet fever nor diphtheria. Next day the temperature fell to normal, but tachycardia became more

pronounced, and the pulse rose to 160 and 200-228, and on three occasions it reached 240 by the stethoscope, it being impossible to take it at the wrist. This rapidity of the pulse persisted without intermission until her death on January 28th, or 16 days. All through her illness she mide no complaint in any way about her heart. She felt no oppression nor palpitation, and her breathing was calm and quiet, not exceeding 32, and she was able to move and sit up, and take ample nourishment without any distress, and she slept well. On the 21st she complained of severe pain in the right leg and foot, with powerlessness, and on the 22nd of intense agony in the calf of the left leg. It was then plain that gangrene had occurred; dry mummification of the left and moist gangrene with bulke of the right foot. Pulmonary congestion - albuminuria with hæmaturia now set in, and she died on the 28th. Very large and oft-repeated hypodermics of morphia were necessary to give ease.

I wish to call attention to the rarity of the condition called tachycardia, the remarkable character of the pulse, its recurrent or paroxysmal features, the length of time life may be maintained, and the paucity of post-mortem examinations, peculiarities which are referred to in various important contributions to the subject by Drs. Bristowe Bouveret, Herringham, and Williams. The condition may come on seemingly without cause, and may attack at any age, 70 to 5 years of age. None of the theories founded on the teachings of physiology, experiment, and pathology quite suit the case of a heart suddenly beating 200-240, and as suddenly, after hours' or days' duration, by day or by night, falling to

70-80.

In conclusion, I may mention that of the six fatal cases which have been examined after death, three showed inflammation or fatty disease of the muscle of the heart, and three dilation: and I may contrast my own case (Case III.) in that the myocardium was perfectly healthy and the organ not dilated. The cause of the gangrene was arterial and venous thrombosis of the iliac on one side after femoral on the other, while the kidneys, lungs, and liver were the seat of infarcts; yet none of these infarcts, any more than the heart itself, showed any bacterio-logical evidence of infective or other microorganisms. The reading of it was probably—first, primary febrile, possibly influenza; second, cardiac weakness as its effect; tachycardia as another possible effect of the toxin on the cardiac ganglia; and third, thrombosis of the right and left auricles, and infarctions (emboli) of the pulmonary and systemic arteries.

Clinical Records.

MERCER'S HOSPITAL, DUBLIN. Three Cases of Diabetes Insipidus.

Under the Care of Dr. Lumsden.

CASE I. was that of a boy, et. 9, who was admitted to Mercer's Hospital, June, 1898; family history good; well nourished, blond, of a fresh complexion, and fairly moist skin; tongue and lips very dry, and he complained of an insatiable thirst; appetite very poor, vomits occasionally after solid food; urinates frequently, and shivers very often before micturition; physical examination reveals no abnormality; pulse intermittent at times, of low tension, its rate varying from 75 to 110; complains frequently of headache which causes him to cry out; of an excitable and emotional temperament, flushes up when spoken to; increased knee jerk, quadriceps reflex slightly present and an attempt at ankle clonus; temperature normal or subnormal. About six or eight months ago it was first noticed. He was drinking large quantities of high third the sidness of the subnormal and the subnormal state. fluid; it did not follow an illness or accident, although

⁽a) Read before the Royal Academy of Medicine of Ireland, May 19th, 1899.

a history of a fall on head three or four years ago is to be obtained. The polydipsia first appeared. While in hospital greatest quantity of fluid drunk in one day was 860 oze, the greatest quantity voided being 750 ozs. On two occasions when fluids were restricted he drank his own urine. The urine was of a pale greenish colour, alkaline or faintly acid; sp. g. 1001-1002. No albumen nor glucose was ever discovered, although daily examined for a period extending over five months. Inosit was not present. Urea varied from 150-600 grains in twenty-four hours. Eyes normal; blood normal. Various treatments were tried in this case, and although his general health very great'y improved and subjective symptoms disappeared when discharged, he was passing from 300 to 400 ounces, and drinking about 300 ounces fluid in twenty-four hours.

CASE II.—A healthy, vigorous looking labourer, æt. 64. Case 11.—A healthy, vigorous looking labourer, æt. 64. Good family history; a violent blow on head twenty years ago, after which the polydipsia and polyuria appeared and has since persisted; given to alcoholic excesses all his life; skin very dry; complains of dryness of mouth and tongue, which is covered with a darkish brown fur; appetite good, but not excessive; organs sound; no cardio-vascular evidence of granular kidney; pulse 72, regular and of distinctly low tension; reflexes alloweigh, complains of frequent, occinital handacha and sluggish; complains of frequent occipital headache and pain in lumbar region; very easily tired, and nervous when up, prefers to lie in bed; drinks from 260 to 300 ounces in twenty-four hours and passes about twelve pints of a pale coloured urine, faintly acid; no albumen: no sugar; density 1003; inosit is present; no casts; eyes examined revealed chronic glaucoma, but no retinitis or neuritis; has somewhat improved on valerianate of zinc,

but still polyuric.

CASE III.—Girl, et. 17, fell on back of head four years ago, shortly after which polydrisis and polyuris. appeared; used to drink upwards of twenty pints a day; on admission she was passing and drinking about four-teen pints daily; pale urine; sp. gr. 1002; neutral; no albumen; no sugar; no inosit; no casts; urea greatly diminished, organs sound; pulse tensions low and no signs whatever of granular kidney. She was first tried on various drugs without good effect, finally on valerianate of zinc, commenced in ‡ grain doses thrice daily and increased gradually till she was taking 22 grains in twenty-four hours. The result was wonderful, the thirst disappearing and urine excretion falling to the normal. She has been under constant observation ever since (four months.) Her general health has improved, she has gained in weight, and there has been no return of the polydipsia or polyuria.

Transactions of Societies.

ROYAL ACADEMY OF MEDICINE IN IRELAND. SECTION OF MEDICINE.

MEETING HELD FRIDAY, MAY 19TH, 1899.

The President, Dr. J. W. MOORE, in the Chair.

NOTES ON THREE CASES OF DIABETES INSIPIDUS. Dr. Lumsden read the notes of three cases of diabetes insipidus, which will be found under the heading "Clinical Records."

The President remarked that two of the three patients were males, which was the usual proportion, though it was more commonly met with much earlier than 64. He mentioned the case of a boy, et. 11, who but slightly improved under treatment for about six

months, but subsequently under treatment for stout six months, but subsequently under treatment a spontaneous cure.

Dr. Walter Smith pointed to the alkaline reaction of the urine, and raised the question of the source of the normal acid reaction. He believed that the normal secretion in the glomeruli of the kidney was alkaline, and that in passing through the convoluted tubes it became acid, though whether this was due to the secretion of acid or the absorption of alkaline salts he did not know. He asked what evidence there was of the presence of

inosit in the urine of one of the cases, inosit having nothing to do with the sugar group, but belonging to the benzene or aromatic derivatives. Great stress had been laid on the relation of nerve injury, especially head injuries, to this disease. In his opinion, however, the only relation of nerves to the secretion of urine was of a vaso-motor sort.

Dr. LITTLE, referring to the occurrence of the disease in old patients, related the case of a middle-aged patient in the Adelaide Hospital who used to pass an enormous quantity of pale urine of low specific gravity, and suffered from intense thirst. He died comatose. Postmortem, the coats af the bladder were much thickened, and the prostate enormously enlarged, the ureters as thick as a child's small intestine, and the kidneys completely excavated, resembling what is known as surgical kidney, but without any ammoniacal magnesium phosphate or pus. The case was peculiar in that there was no cystitis nor evidence of inflammatory changes in the

bladder, the ureters, or pelvis of the kidney.

The President mentioned that the infectious fevers seemed to have a remarkable influence on diabetes insipidus, and a cure had been known to occur after one of these fevers, which they knew often affected the vaso-

motor functions considerably.

CLINICAL INVESTIGATIONS ON WIDAL'S REACTION AS A DIAGNOSTIC IN TYPHOID FEVER.

Dr. Littledale gave an account of 120 cases on which he had tried Widal's reaction. At first the blood serum and typhoid bouillon were mixed in the proportion of 1 to 10, but this was found quite useless, as cases other than typhoid gave an agglutination Later the proportion used was 1 to 40. reaction. Results were divided into positive, negative, and doubtful, but there were only a few of the latter, and these would have probably been eliminated if higher diluwould have probably been eliminated if higher than the tions were used. Three cases of diphtheria that had received antitoxin gave an agglutination reaction, as did also antidiphtheritic serum itself. Typhus and the complete always gave negative results. The acute tuberculosis always gave negative results. The conclusion arrived at was the unquestionable value of the test when applied in the second week, as the earliest case tested was on the fifth day of illness, and when a dilution of not less than 1 in 40 is used.

Dr. M'Evoy insisted on the fact that Widal's was essentially a quantitative reaction. A German investigator in a recent paper in Berlin claims to have got a reaction before Widal's reaction could be obtained. This he accomplished by making cultures with gelatine from the faces, and, on submitting them to a temperature of 72 degs. for three hours, he states that there is an appearance in the colonies perfectly distinct from the

bacterium coli communis.

Dr. Finny said there was often great difficulty in diagnosing typhoid fever from tuberculous disease. case in particular he remembered in which the patient had all the symptoms of tuberculous meningitis, but the application of Widal's reaction gave a positive result and a necropsy confirmed the diagnosis, as the ulcers could be seen in an advanced stage of healing.

Dr. LITTLEDALE, in reply, said he had no experience of the test that Dr. M'Evoy had spoken of. He was informed, however, that Gartner's bacillus, which in all probability belonged to the race of coli bacilli, clumped long before the typhoid bacillus. It was always very difficult to isolate the typhoid colonies in the fæces.

THREE FATAL CASES OF TACHYCARDIA.

Dr. Finny read a paper embodying notes of three cases of the above, which will be found on page 640.

The President remarked that the healthy condition of the heart, notwithstanding the symptoms during life, was notable, as the occurrence of these lesions was usually associated with changes in the heart muscle. He believed that the diagnosis of influenza would fit in with Case III., and the tachycardia could be accounted for by the profound nervous disorder which influenza was apt to cause.

Dr. W. LANGFORD SYMES in this connection referred to an account of a case of "thrombosis and embolism in fatty heart," which he had contributed to The Dublin

Journal of Medical Science for 1892.

Dr. Knorr said he had an opportunity of observing an extreme case of tachycardia in a lady, æt. about 30. She had always been of a neurotic temperament and suffered frequently from epileptiform convulsions. The action of the heart became often excessively rapid; so quick, in fact, that it was impossible to count the pulse.

Dr. Little said that genuine cases of tachycardia were comparatively rare, and those he had seen were characterised by considerable distress, thus differing from Dr. Finny's cases. He cited a case in which the patient lived for eight or nine years after the first attack. During the intervals of five or six weeks between the attacks the patient seemed perfectly well. At first no physical signs of disease of the heart could be detected, but one day he discovered a slight diastolic aortic murmur, which increased until it became quite plain. The only thing that gave him relief was brandy. Another case was that of a lady who died suddenly during the last attack, which had lasted for twelve days. She had been ailing for five or six years, and he could detect nothing wrong with her heart. He knew of no drug which had any effect on this condition.

Dr. Finny, in reply, said the duration of cases for eight or nine years he knew to be exceeded in some instances. One of Bristowe's cases lasted for fifteen years, and in the intervals the patient was perfectly well. Brandy seemed to be the favourite drug, and he had found a cup of strong coffee or a draught of cold water often beneficial in stopping the attack.

The Section then adjourned.

PENETRATING WOUNDS OF THE CHEST.

AT the Academy of Medicine, M. Delenue spoke on the treatment of penetrating wounds of the chest. greater number, he said, of pulmonary wounds produced by bullets, swords, or other similar instruments get well without difficulty. The treatment of these wounds, whether they be simple or complicated with hæmorrhage, hæmoptysis, hæmothorax, the presence of the bullet, &c., should be first absolute immobility and antiseptic occlusion of the wound, and, secondly, according to the nature of the symptoms observed, the employ of Morphia was particumorphia, ether, caffeine, &c. larly indicated in the form of injections in wounds resulting from duels. In these persons, the inward struggle of passion, amour propre offended, the efforts to appear cool and collected produce, along with the pain of the wound, a loss of nerve power which predisposed to fainting. It was consequently preferable to treat these patients on the spot, at least for the first few days, the shock and effort of transportation to a distance exposed them to hæmorrhagic accidents and notably increased the suffering.

Injections of artificial serum constituted a powerful means against the anæmia following hæmorrhage on the condition that they were neither too rapid nor too abundant, as otherwise they might provoke congestion of the lung and increase the dyspnæa.

In severe pulmonary hæmorrhage, in hæmothorax, threatening the existence, the usual methods employed for arresting slight hæmorrhage would scarcely be relied upon; direct intervention should be advised, ligature, suture, plugging, compression. The fear of a complete pneumothorax should not paralyse the action of the surgeon, for according as the lung was retained to the

walls by adherences or otherwise, this pneumothorax existed already or would not be produced at all. The exposure of the lung would allow the operator to treat simultaneously by suture or plugging the traumatic pneumothorax and the hemothorax.

M. Championnière agreed with the observations of his colleague, except on one essential point—intervention. He was convinced that the patient ran more risks from an operation than by being immobilised. He knew two individuals who bled profusely from wounds in the lung and who recovered by immobilisation, and he did not hesitate to say that if their thorax had been opened in order to tie the severed vessels, they would have succumbed. It should not be forgotten that wounds of the pulmonary organ, even of a considerable extent, unite spontaneously when abandoned to themselves, and on the other hand they bled indefinitely when irritated. In the state of collapse, in which the patient generally is under these circumstances, pleurotomy was, in his opinion, a very grave operation.

FRACTURE OF BOTH CLAVICLES.

M. Guinard related the case of a young man who, caught between two waggons, suffered violent lateral compression of the thorax. Both clavicles were fractured by the accident. The patient recovered very rapidly, but with a considerable amount of deformity.

INCONTINENCE OF URINE.

Besides the incontinence of urine symptomatic of a material lesion of the urinary tract, there exists, as is well known, an incontinence called essential, with any apparent lesion or anterior affection. In certain subjects the bladder is particularly sensitive, and the muscular fibres do not permit of extension beyond a certain limit. If it is exceeded the individual isforced to urinate. During the night sleep renders this sensation of the want to urinate still more obtuse, the child takes no notice of it, and wets the bed. According to Guinon incontinence of urine was a stigmate of nervous heredity, for in nearly all the cases can be found hereditary antecedents in the parents who had suffered from hysteria, chorea, or other nervous affections. The medical anti-nervous treatment should consequently be the principle of the therapautics. Bromide of potassium, valerian, belladonna, &c., frequently good results are obtained by pills containing ergot of rye, iron, and a little belladonna.

Germany.

[FROM OUR OWN CORRESPONDENT.]

BERLIN, June 16th, 1899.

At the Congress for Medicine after the subject of cardiac insufficiency had been lengthily discussed that of the

EARLY DIAGNOSIS AND TREATMENT OF ANEURYSM was brought forward by Hr. Moritz Schmidt, of Frankfort. He said the earlier aids to diagnosis rendered one possible with tolerable certainty, but two new aids permitted one with almost absolute certainty. One was the so-called "tugging" discovered by Oliver, Cardarelli, and the Rontgen rays. Tugging was a dragging down sensation best observed when the annular cartilage was slightly pushed up by the index and middle finger of the right hand, the patient's head being somewhat extended backwards at the time. He considered the symptom

an exceedingly important one, Cardarelli believed it could be felt in the case of even very small aneurysms. It remains to be determined whether it could only be felt in aneurysms of the ascending aorta when the tumour was attached to the wall of the traches.

Positive results with the second named aid were announced from all sides. The earlier known signs. however, still remained, dulness over the manubrium sterni, pulsation especially in the first and second interspaces, differences in the radial pulses, in fulness and Auscultation gave less distinct indications. Very often no murmur was heard, and when heard it might arise from pressure on the aorta by a tumour.

The differential diagnosis was especially difficult. Sarcomata might cause very lively pulsation and aneurysm none at all. The diagnosis was most likely correct in individuals between 45 and 60 who presented the symptoms named, and who had been infected with syphilis. The differentiation from a diffuse dilatation of the descending aorta was the most difficult.

As regarded atiology there was the same variety of view as in tabes. That syphilis attacked the arterial walls in the form of thickening there could be no doubt. The commencement of the aorta was a favourite seat of the change. The changes in the intima differed from those of arterial sclerosis in the absence or minimal amount of chalky deposit. There were preparations, however, that showed both processes. As a result of syphilis, probably through disease of the vasa vasorum a disturbance of nutrition took place in the media, with destruction of the elastic fibres in circumscribed spots, in which the cells were arranged in the form of cell heaps (sclero-gummatous tissue or milliary gummata) The loss of substance in the muscular and elastic structure was replaced by connective tissue, which "gave" more readily to the stress of the blood stream. intima was not suitable for successful resistance. By weakening of the media neither was in a position to do its proper duty. It was not probable that aneurysms arose from arterio-sclerosis alone, otherwise they would be found more frequently. Some investigators of the first rank did not believe in the ætiological influence of syphilis. Virchow had spoken against this influence last year. Straining and wounds specially favoured the occurrence of aneurysm in those thereto inclined, as was shown by the great number of men affected. Only in Bavaria were they more frequent in women, because there these did the hard work.

He could confirm the favourable influence attributed to potassii iodide, especially in not too small doses, 3 to 5 grms. pro die. An alternation with sodium and ammonium iodide was proper, and in the early syphilis it should be associated with inunction. After healing of the diseased part in the media the connective tissue underwent cicatricial contraction and the aneurysms became smaller. The sac did not, however, become filled with firm clot. The starvation treatment also assisted. Possibly the results of the anti-syphilitic treatment were due to lessened nourishment, independent of the action of the basic disease. By experiments on starving animals it was shown that diminished nourishment affected the blood pressure, probably by diminishing the quantity of the blood. The pulse became smaller, the blood itself became thicker, the number of red blood corpuscles increased, with which the increase in hamoglobin went hand in hand. In secent years, chloride of calcium in

doses of 2 grms. had been given to increase the coagulability of the blood and the inhalation of carbonic acid gas. In Paris, the coagulability is said to have increased in two cases by injection of gelatine, but soon after communications appeared showing that the procedure wasdangerous. In one case the patient died suddenly of embolism. The speaker was strongly in favour of trying Tufnell's starvation treatment, it decidedly influenced the coagulability of the blood. The patient should not be placed suddenly on these diminished caloria, but one could go on fairly rapidly. The action of the treatment was comprehensible when it was borne in mind that recovery sometimes took place spontaneously in the course of exhausting diseases. For the treatment a great amount of energy was necessary on the part of both physician and patient-The quality of the fluid was best varied. A valuable complement of the Tufnell treatment was absolute rest in bed. It was best to continue the low diet and rest in bed at least eight weeks. Then gradual relaxation of strictness might be allowed. Here also the maxim was in force—varietas delectat. Should such a patient during or after treatment be attacked with catarrh, the cough must be kept down by opiates in larger than ordinary The speaker had observed two patients get worse through attacks of cough. He looked upon electrolysis as the best means at present known of bringing about coagulation in the sac. It should not be employed only in the early diagnosed, still small aneurysms; even in the large ones it effected considerable improvements and long-lasting recoveries.

Hr. Hausemann, Berlin, complained that only a onesided inquiry was made how many people suffering from a particular disease had previously had syphilis. With an inverse procedure surprising results would often be obtained. During the last four years he had dissected sixty-four cases of aneurysm; in twelve there were traces of former syphilis. Of these twelve, however, only two died of their aneurysm; in the other ten the aueurysm was an accidental discovery, and in an early stage of development. On the other hand, during the same period 350 autopsies had been made in which there were indications of early syphilis. Of the syphilitic cases, therefore, only 3:43 per cent. developed aneurysm, and only 0.57 per cent. died of it. It was not proved that syphilis could cause aorticaneurysm. Syphilis might render dilatation of a vessel possible, but he could not recognise syphilis as a chief cause of the disease. Potassic iodide influenced the coagulability of the blood, and cicatricial tissue formed in the blood clot.

VIBNNA, June 17th, 1899.

MECHANICAL TREATMENT OF HEART DISEASE.

AT the "Gesellschaft der Aerzte" Herz read an exhaustive history of the various methods that have appeared and disappeared for the mechanical treatment of heart disease, among which were Schott's, Oertel's,

Unhappily for science those names had been grouped in schools of a very dogmatic character that did not promote the progress of science, though all of them had very good objects in view. The practitioner who would

right treat his case should select the good from all and treat it rationally from a practical point of view. All generally admit that the blood pressure in the systemic circulation is not to be reduced, but, on the other hand, increased if possible as measurement of arterial pressure in these cardiac imperfections show a reduction of the normal blood pressure.

The fundamental idea in all these methods is to stimulate and raise this pressure by gymnastic exercise or definite movements, according to the whim of the particular school under consideration. We find, moreover, that the very same movement produces very different effects according to the records of the individual schools which should not be the case if all were effectual. He next analysed the methods into movements of resistance, progression or traction, voluntary, co-ordinating, and passive, and concluded by remarking that the form adopted was not so much to be considered as the manner of application.

The gymnastic treatment is not so generally applicable as the other forms, except in cases of fatty heart. Oertel's mountain climbing might be grouped under the progressive treatment, and which is often accompanied with good results. Herz has found by experiment that this treatment is equally beneficial in fatty conditions of the heart. Where there is vascular disturbance with enfeebled activity of the cardiac muscle, associated with valvular deficiency, the voluntary movements recommended by Schott, of Nauheim, is preferable. For this form of treatment Herz proposes an apparatus for toning the muscle and increasing the vigour of the central nerve system. The progressive form serves to calm the whole organism by presumably acting on the nerve system.

In the discussion that followed Exner drew attention to two forms of treatment recommended by Bum and Herz which they have founded on the phenomena obtained by experiment that the influence of muscular labour has a marked effect on the breathing. They are of opinion that the dyspness produced by muscular effort is due to an irritation derived from the decomposed products of the active muscles which act on the medulla oblongata. They have found by experiment that blood taken from animals in this dyspneic condition and injected into others in a healthy state will produce similar dyspnea. He thought we had ample evidence physiologically and physically in mountain climbing. The elements of muscular change were different on descending hills, and produced a form of contraction somewhat similar to an elastic band round the body, with a feeling of falling backwards. Both forms of exercise have apparently different products. In climbing hills there is weariness, perspiration and dyspnœa; in descending hills there is similar weariness, perspiration, but no dyspnœa. therefore concludes that the products eliminated are different, and that the therapy will influence the heart in a different manner.

Knoll remarked that in ascending hills the forward inclination of the body would affect the diaphragm differently than when descending, and probably explain the dyspness.

BOWEL INNERVATION.

Pal recorded his experiments on animals in producing tonic contractions of the bowel after cutting the splarechnic nerve, and irritating the root or stump. These experiments were similar to injecting strychnia, or a suprarenal extract. The experiments were conducted with an india-rubber ball in the bowel, from which the movements were transmitted to a water manometer, to which is attached a revolving diaphragm that imparts to paper a graphic description of the movements.

CAPE Town, May 27th, 1899.

GOVERNMENT AND THE COLONIAL HOSPITALS.

THE Premier, who, as Colonial Secretary, is ministerial head of the department dealing with medical matters, has intimated to the hospitals of the colony that, in future, they will be subject to inspection by a Government officer, upon the nature of whose reports will largely depend the amount of Government grant. It may be explained that, although all the colonial hospitals, with the exception of that at Kingwilliamstown (primarily a native hospital), are now managed by local boards, these boards receive large Government grants, usually far in excess of the income derived from local sources. For instance, the New Somerset, at Cape Town, only raised last year under £3,500 from subscriptions and paying patients, as against £10,000 Government grant. The Colonial Secretary partly guards Government interests by having two or three nominees on each board, but as these are local men, the control is very lax, and the local Dogberries are apt, very often from sheer ignorance, to perpetrate extraordinary vagaries, as we have not yet educated that class of fairly competent lay administrators, so generally available in England. The interests of the profession are generally absolutely ignored, except when some particular local medico is a power, and he then usually runs the establishment for his own private benefit. At one of our most important hospitals, that of Grahamstown, attempt to place the whole control in the hands of one local medical man was only recently just defeated by a most regrettable, although necessary, agitation, during which the said medical man calmly stated that he was not going "to show his hand to his neighbours" ty allowing them to see his operations. Sanitation is often very bad, and the provision for the training and accommodation of nurses, except in two or three hespitals, far from what it should be. Medical appointments are purely a matter of local influence. Under these circumstances, a certain measure of Government supervision will be welcomed by the profession, especially if the inspection be, as it is likely, in the hands of the chief of the Health Department, Dr. George Turner, a broad-minded and thoroughly capable man not afraid of speaking his mind.

THE NURSING QUESTION.

There has been a good deal of newspaper correspondence lately about the nursing arrangements at the New Somerset Hospital, where the antiquated system of using nurses as housemaids and scrubbers is still in vogue. This institution is hopelessly behind the times, and most colonial aspirants for nursing prefer repairing to Kimberley or Port Elizabeth, both well-conducted

Digitized by Google

nursing schools, to training at Cape Town, with all its climatic and social avantages.

The controversy referred to in my last communication about the proposed enclosure of the catchment area on Table Mountain is in fair way of being arranged. A large deputation waited upon the City Council the other day, and that body showed some signs of modifying its original ideas in the direction of only enclosing the reservoir and its actual tributary streams.

THE BUBONIC PLAGUE.

At the last meeting of the Cape Town Branch of the British Medical Association, Dr. Turner, the Colonial Medical Officer of Health, read for his assistant, Dr. Gregory, a paper on the case of Bubonic Plague which occurred in the Transvaal some three months ago, with illustrative specimens under the microscope. He had no doubt as to the diagnosis of the case, although he mentioned that Mr. Theiler, the Transvaal Government Bacteriologist, a veterinary surgeon, by the way, disagreed with him. The course of the case, its symptoms, and the microscopic appearances seemed conclusive as to the case having been truly one of plague. Dr. Turner thinks that the infection was contracted at Delagoa Bay, where, he believes sporadic cases have been occurring for some time. He attributes the absence of an epidemic to the stringent precautions taken by the Portuguese medical authorities, who, although they deny that these cases are plague, treat them exactly as if they were.

At the same meeting a committee was appointed, on the motion of Dr. Darley-Hartley, who has been agitating the matter for some time, to report as to the practicability of initiating some scheme of medical education in Cape Town. In the idea in the minds of those interested is to form a Post-Graduate School, badly wanted nowadays, as the task of raising money to proceed to England for study is getting, for most men, harder every year, and to provide a first year's curriculum for the student.

There is a recrudescence of small-pox at Johannesburg. Twenty natives died last week, and there are at present in the lazaretto three whites and about 150 Kaffirs.

The City Council of Cape Town is erecting a very complete infectious diseases hospital at Green Point, just out of the city proper.

The Rhodesians are making medical matters a prominent feature in their newly acquired self-government. Thanks to Dr. Hans Sauer, a member of the Council, the Administrator has promised assistance to the School of Tropical Diseases, a Contagious Diseases Bill, and a Bill for the Regulation of Dentistry and Pharmacy.

The recent supplementary elections have added two medical members to the Cape Parliament, Dr. Smartt and Dr. J. H. Meiring Peck, the latter President of the Colonial Medical Council. We have great hopes that he will insist on due attention being given to medical legislation. The profession is now represented in the Assembly by the Speaker (Dr. Berry) and six other members.

FORMAL notice has been issued of the termination of the official existence of the "Board of Control of Irish Lunatic Asylums." It will remain "unwept, unhonoured, and unsung."

The Operating Theatres.

ST. PETER'S HOSPITAL FOR STONE.

URETHRAL PROSTATECTOMY.—Mr. SWINFORD EDWARDS operated on a man, æt. about 50, who for the past ten years had had difficulty in emptying his bladder. At time of admission his residual urine amounted to 12 ozs., for the evacuation of which he had to pass a catheter two or three times a day. His urine was normal. On examination per rectum the prostate did not appear to be enlarged, but on sounding with a short beaked sound one could feel that the prostate was producing an obstruction at the neck of the bladder known as the condition described by Thompson as "bar at the neck of the bladder." The patient having been anæsthetised, Mr. Edwards introduced Gouley's prostatome, which is an instrument on the principle of a lathotrite, the difference being that the male blade is sharp, and when screwed home is received into the female blade; instead of crushing it would therefore punch out a piece of tissue. The instrument, once in the bladder, was reversed, the blades unlocked, and the female blade made to hug the back part of the prostatic bar. The male blade was now withdrawn for about an inch, and the sharp concealed pin pushed forwards to fix the piece of prostate to be removed. The male blade was next slid forward until it engaged the obstruction. The instrument was then locked, and screw force applied, by which means a piece of the obstructing bar was removed. This manœuvre, after withdrawal of the instrument, was repeated twice, although the repetitions were not so successful in removing tissue as the first one. There was not an excessive amount of bleeding, and the operation was completed by washing out the bladder with a weak solution of acetate of lead. The amount of tissue removed in all equalled in size a small white bean. Edwards remarked that the only difficulty about the manipulation was to keep the instrument well pressed down on the prostate when pushing home the pin, as the instrument was very apt to ride up and so make it difficult to catch and punch out the required amount of prostatic tissue. He also thought that the instrument could be improved upon by having the male blade made a little longer by which means more prostatic tissue could be removed at one application. In describing the uses of this procedure he said it was now some years since he had employed it; he had operated in some three or four cases of prostatic hypertrophy, in all of which the power of micturition had been improved for a time, the good results, however, had not been permanent, owing, perhaps, to the fact that the cases selected had not been favourable ones, in other words, that they were probably cases of general prostatic hypertrophy rather than what he considered to be the condition of this case—namely, "bar at the neck of the bladder." This bar is not always easy to diagnose, he said, the condition having to be determined by the absence of marked prostatic enlargement coupled with the presence of symptoms pointing to prostatic obstruction, which obstruction is corroborated by careful examination of the vesical neck with the aid of a short beaked sound in the bladder, and the presence of a finger in the rectum.

THE INFLUENCE OF CLIMATE AND PLACE UPON SYPHILIS.

If there is a disease whose virulence has been modified at different periods by climate and place, that disease is syphilis. The literature of the subject abounds in instances in which such modification is shown, and further there is much evidence to prove that in the treatment of syphilis by mercury better results are obtained when the climate is warm and dry than when it is cold and Writing as long ago as 1787 Swediaur remarked that this explained why persons who could not be cured of "venereal disorders" at St Petersburg or Stockholm became well when they went to Italy or Portugal. He further states, "We may be authorised to believe that the influence of a warm climate upon those infected with lues venerea is not inconsiderable; that it may retard the progress of the disease; that it may render it milder in some of its symptoms, and also that it may contribute to increase the activity and certainty with which the proper remedies operate, and thus render the patient in less danger of suffering from some of the sequelæ which often prove as troublesome as the original complaint." That full knowledge of the facts relating to the advantages to be derived from the climatic treatment of syphilis should have been extant, as early as the sixteenth century is not a little significant—and it is certainly not without interest to note that in the present day the value of such treatment is still recognised. The whole subject is discussed in a comprehensive paper by Dr. Shaw-Mackenzie in the April number of the Journal of Balneology and Climatology. He reproduces from the earliest times in the history

of syphilis the recorded observations bearing upon the point, and in doing so brings to light some curious reflections and facts illustrative of the experience of our forefathers in connection therewith. Perhaps the quotations which he gives from Fergusson's works are the most interesting; of late this authority has received a good deal of attention from the prominence accorded his writings by Dr. Shaw-Mackenzie, and there is no doubt that Dr. Mackenzie has distinctly performed a useful service to those interested in the subject by unearthing the views and critical observations of an authority like Fergusson, who had every opportunity of studying the disease from its practical aspects. The striking feature about Fergusson's work is not only its originality but the conviction which it conveys that his conclusions are nothing more than the outcome of his actual experience. Fergusson was no mere desk worker-compiling ideas at his desk, and publishing them to the world afterwards as actual facts. He seems to have set himself the task of simply placing upon record everything that experience had taught him about syphilis, and the solidity of his reasoning regarding facts within his knowledge shows unmistakably that he had no other motive to serve beyond that of re cording the truth. It is from this aspect that Fergusson's work must be regarded as of so much value in the present day. In the course of his paper Dr. Mackenzie refers to the de novo origin of syphilis, but the reference is merely a casual one. It would be interesting, however, to learn from him to what extent such a theory can be substantiated, either by personal observation or recorded cases. To describe a disease in these days as arising de novo, is apt to court opposition, inasmuch as bacteriology has taught us to discount statements of this kind. So far, it is true, bacteriology has not been able to do much in elucidating the fons et origo of syphilis; but, however this may be, while a great deal is still anknown regarding the syphilitic virus, the character of the disease unmistakably stamps it as having a microbic origin. In conclusion, we cannot do better than refer those who are interested in the subject of syphilis to Dr. Shaw-Mackenzie's interesting paper.

THE ENGLISH LOCAL GOVERNMENT BOARD AS A CENTRAL AUTHORITY.

THE exact position of the Local Government Board as a central authority with regard to the district administrative bodies is one of considerable importance. Clearly, it must now and then happen that the public affairs of a district will fall into unworthy or incompetent bands, in which case the absolute need of control by a higher power will become painfully apparent. Hitherto the Local Government Board have played the part of the indulgent parent who has rarely stepped beyond the bonds of sparse and gentle chiding, however great the errors of his offspring. The policy of the board, in short, has, more or less, been of that conservative kind which lies at the root of every branch of British administrative government. Nor can it be

denied that the record of this Department has been of a brilliant and solid nature, but for all that it has been for a long time apparent that some alterations were necessary in order to bring its work abreast of the times. The chief complaint against the Board has been the want of initiative. Their machinery of inspection has been perfected, but the reports of the inspectors have been pigeon-holed, and their advice to local bodies in many cases has fallen on rocky ground. The ill-effects of this purely advisory system have been most apparent in the case of local Poor-law boards who have refused to bring up workhouse and infirmary buildings and administration to proper standards, of guardians who have failed to administer the Vaccination Acts, and of defaulting sanitary authorities. Of late, however, there have been signs that a new era is at hand in the history of the hydra-headed Department at present presided over by Mr. Chaplin. Various local bodies have been sharply reprimanded and given to understand that passive resistance and dilatoriness will no longer be permitted to stand in the way of necessary action. This new departure was illustrated last week in the shape of an ultimatum sent by the Board to the Rollesby Guardians. The serenity of that rural authority was roughly shaken by an official intimation with regard to the provision for sick paupers to the following effect. "This matter has repeatedly been brought before the guardians, and the Board cannot permit of any further delay in suitable provision being made for this class of inmates. The Board must state that unless the guardians are prepared to undertake to deal adequately with the several points mentioned in the Board's letter of April 21st last, they feel it their duty, without further warning, to take steps as indicated in This tbat letter." communication good deal of surprise to its recipients, among whom we learn "it was the subject of considerable discussion." There is a refreshing ring about the tone of the letter which it is to be hoped will serve as an example to other boards that trust to the methods of dilatoriness and evasion that have hitherto proved efficient weapons in the hands of rebellious local authorities. The whole question of the relation of guardians to the central authority is one that should be definitely settled. Are the guardians simply the trustees or the representatives of the ratepayers, and as such empowered to administer the Poor-law according to their own will and interpretation; or do they exist only as ramifications of a great central administra-From the Norwich newspapers we gather that these considerations have presented themselves to the wisdom of the Rollesby Board as fit subjects for discussion at the forthcoming Poor-law Confer. ence to be held at Ipswich. It is to be hoped that the new policy of the Local Government Board foreshadowed in this incident may meet with the success it deserves. To replace abstract advice by active compulsion means a reform of prime importance which must necessarily be carried

out with due caution and deliberation. Take case of the Medical Officers of Health, who are in many instances made the scapegoats of negligent sanitary authorities, and who have so far looked in vain to the Central Foard for assistance. It seems clear enough that something should be done in defence of those officers, and it is equally beyond doubt that any such interference demands the exercise of the highest form of diplomacy in practical administration. A great step towards the perfection of Local Government Board administration would no doubt be achieved by the separation of the Poor-law branch from that of the Public Health. Meanwhile, we must be content to leave matters in the hands of a department that, in the midst of many dangers, has, on the whole, steered a course of conspicuous safety.

ANTI-STREPTOCOCCIC SERUM IN THE TREATMENT OF PUERPERAL FEVER.

THE report of the Committee appointed by the American Gynæcological Society to consider the subject of anti-streptococcic serum in the treatment of puerperal fever is not very encouraging reading. Taking the figures from all available sources, with their many possible and probable fallacies, the results are far from reassuring, indeed it is doubtful whether the serum can be credited with any tangible effect in averting the fatal consequences of puerperal infection. We will not go so far as to assert that the use of the serum must be abandoned, though the report affords little excuse for hope, because it is possible that the limited use so far made thereof may explain to some extent its alleged inefficacy. For instance, it is probable that, as a rule, it is employed only in very pronounced cases of streptococcic infection. at a stage when no human intervention can obviate the toxic effects of the infection. It is also suggested that one cause of the still high mortality is that many observers associate the employment of the serum with other means of treatment, notably with the use of the curette, which is regarded by some authorities as of itself a fertile source of mischief In this they probably do the curette a wrong. The curette is unquestionably a valuable means under certain circumstances, of preventing septic mischief after childbirth. Intelligently and opportunely used it enables the practitioner to remove from the interior of the uterus decomposing fragments of placenta and membrane which, if left therein, serve as for the proliferation of the infecting organism. Once infection has taken place, its use can only be a matter of secondary importance. It is conceded on all hands that the curette is an instrument requiring to be used with prudence and care, but we cannot lend support to those who would rashly condemn it under all circumstances. It is the old question of meddlesome midwifery. It is imperative to interfere in certain conditions, it is as desirable not to interfere in certain others, and the choice of intervention or non-intervention must lie with individual practitioner who is called upon to

deal with the case. Reverting to the serum treatment one plausible explanation of its inefficacity is that there is not one streotococcus but several, and that the serum which is operative against one pathogenic variety is powerless against another, It this be so then the serum treatment of puerperal fever and of sepsis in general is indeed unlikely to yield any measure of success. Unfortunately, this is what one's experience of the so-called "mixed" infections would ead one to expect. The value of anti-diphtheria serum in cases of pure diphtheria is now pretty well established, but its use will not prevent a fatal issue when the streptococcus has allied itself with the micrococcus. It may, however, be possible to discover sera which will protect against whole families of bacteria, as well as against particular members of the families, since these have certain biological characteristics in common. In the meanwhile, we must concentrate our attention on the prevention of sepsis, seeing that its cure is still beyond our reach. In this department much remains to be done, especially in the domain of private obstetric practice, where antiseptics have not as yet yielded a tithe of the benefits which they are capable of affording, as evidenced by the results obtained in lying-in hospitals. This fact remains a standing disgrace to midwifery practice, and it will be interesting to observe, in years to come, whether the registration of midwives has any effect in reducing the lamentable and highly preventible mortality from this source.

Rotes on Current Topics.

A Romance of Medical Registration.

THE final scene in an interesting little professional drama was enacted at the recent meeting of the General Medical Council when the name of Mr. Samuel Bingham Shekleton was struck off the rolls. The story is amusing as well as instructive. In 1866 a certain Edward Joseph Nugent obtained the licence of the Royal College of Surgeons, Ireland. emigrated from Dublin in a year or two and set up in practice at Woolwich. After a few years there he moved to Canning Town, where he traded at the address of a quack named Rowlands whose practice it is suggested that he "covered" for several years. In 1895, however, he decided to migrate to the Colonies, where he got his name registered in the local Colonial Register by showing the authorities the entry in the British Register, and, forthwith, he started practice. When leaving England, however, he left his diplomas in charge of his wife, who, with or without her husband's knowledge, rented them to Rowlands, the quack, for 3s. 6d. per week, who was thus enabled to successfully personate Nugent, the name of the latter still appearing in the Medical Register. After a couple of years, however, the Registrar had reason to suppose that Nugent was not at Canning Town, and, accordingly, in conformity with Clause 14 of the Medical Act, he addressed a letter to him at that

place, and, not having had a reply within six months, he struck the name out, as the law obliged him to do. This proceeding deprived Rowlands of the power of recovering fees or signing death certificates, and he was driven to take means to have the name restored. Meanwhile he seems to have employed a Mr. Samuel Bingham Shekleton, also a Licentiate of the same college, to "cover" his practice, which he did, living professionally in the same house in Canning Town; but the arrangement does not seem to have worked satisfactorily, so that Rowlands made up his mind to the bold step of applying for re-registration as Nugent. To carry this through he required to produce a sworn certificate of identification as Nugent, and Mr. Shekleton supplied this false certificate upon the production of which Nugent (alias Rowlands) was immediately reinstated, and his name now appears in the Register. Probably Rowlands's game would have gone on very smoothly but that he killed a parturient woman by the grossest malpractice and negligence, and, the Crown having prosecuted at the instance of the coroner, the whole story, which we have given, came out. Rowlands was sent to gaol for four years, and Shekleton has been struck off the rolls for having given the false certificate of identification. His defence was ingenious, if not credible—i.e., that, though he knew Rowlands for twenty years and worked in his house for the past four years he never knew his name, but always called him "the doctor." When asked why, in that case, he swore that the man's name was Nugent he could make no reply. understand that the Council of the Irish College has followed up the action of the General Medical Council by calling on Shekleton to show cause why his licence shall not be suspended.

The Cancer Society.

As we have remarked in these columns upon more than one occasion, a greater need exists for inquiry into the causes and preventive measures of cancer than of tuberculosis. Great as is the mortality from the latter disease, it is as nothing in comparison with the irresistible, agony-dealing ravages of the former, and while much regarding the etiology and channels of tuberculous infection is known, our information in the same regard concerning cancer is sadly meagre. We are glad, therefore, to note that some effort is now being made to draw public attention to the necessity of taking active steps towards remedying this deplorable state of affairs. Under the presidency of Sir Charles Cameron, Bart., M.D., M.P., a Cancer Society was formed last week at a meeting held at the St. Martin's Town Hall, The objects of the society are the improvement of technical medical education; popular instruction in elementary health laws bearing upon the prevention and cure of cancerous disease; the foundation of a special laboratory for cancer research; and, last but not least, the promotion of a Parliamentary inquiry. This latter point is one upon the urgency of which we have insisted for some time. There can be no doubt that much valuable information would be

forthcoming were a Royal Commission to be appointed to inquire into the whole subject of cancer. A committee of investigation might be appointed, with instructions to visit European and other countries in which cancer is most prevalent, with gleaning facts in regard VIAW to to the cause of its dissemination. It is in the highest degree a reprehensible policy to do nothing in this important matter; the Government must be stirred up to see the necessity of taking action. In a few years more there is every prospect of the mortality from cancer exceeding that of any other disease. Yet, despite its virulence, the disease is allowed to pursue its evil way without any official encouragement being offered to advance our knowledge of its etiology. We trust that the Cancer Society will prosper inasmuch as its objects are most praiseworthy and deserving of general support.

Sweating the Medical Profession.

A WRITER to the Newcastle Daily Chronicle last week addressed some pithy and caustic remarks to the readers of that journal. Under the nom de plume of "MR.C.S." he alluded to the triumphant announcement recently made by the Dean of St. Paul's, at a meeting of the Metropolitan Provident Medical Association, to the effect that considerably over 30,000 members had contributed £5,300 a year. Taken at the figures mentioned, each individual has paid four-fifths of a penny per week for medical attendance and medicine. Well may "M.R.C.S." ask if that is thrift. "Is it not," he adds, "rather sweating—sweating the medical profession? Is it even good policy? In the long run it is the sweater that suffers. The sweated one, to live at all, is obliged to scamp his work, and to use the poorest and cheapest of materials." Some day it is possible that both philanthropists and the recipients of cheap or gratuitous medical services will see matters in their true light. A snap-shot diagnosis and a bottle of physic prescribed after a three minutes' consultation may suffice to stay the fierce desire of the professional philanthropist to minister to the medical wants of the poor, but it certainly does scant service to the latter, and spells ruin to many a struggling general practitioner. We wonder how the churchman who congratulated the Metropolitan Association would tolerate an arrangement that placed a number of his own cloth day and night at the beck and call of thirty thousand poor parishioners at the rate of less than a penny a week. Why should not philanthropists provide the poor with cheap law and divinity in their own homes? or must we regard medicine as the only permanent charitable necessity for our working population?

Phthisis and Alcohol.

THE more diseases to which human flesh is heir whose origin can be traced to alcohol, the stronger becomes the case of the advocates of the temperance A French observer, for example, has just been investigating the connection between alcohol

and phthisis, and in the case of seventeen phthisical patients he ascertained that no fewer than sixteen had been at some time great drinkers. All of them drank brandy or rum, and absinthe. There is now. the opportunity for some one to make similar inquiries into the subject in this country. It would be interesting to learn how far English statistics would compare with those obtained in France. The conditions, however, would scarcely be identical, for absinthe drinking is practically unknown in England, while the French people are less addicted to drunkenness from beer than is the case in this country.

Mr. Kipling's Health.

It is nothing more than natural that Mr. Kipling should still feel the effects of the terrible illness through which he passed some months ago. It is probable, indeed, that many more months will have to elapse before he will regain that measure of health to which he was accustomed before his almost fatal illness seized him. In order to further recruit, however, he will sail this week from New York for England, with a view to passing the summer at his home near Rottingdean. All Mr. Kipling's admirers will wish him that restoration to health which he hopes to attain, without which, doubtless, it will not be possible for him to continue his literary work. A personality so interesting to the world as Mr. Kipling's has become makes it rather a notable fact that he should have determined to place himself within the clutches of our much-abused climate, even in summer. while in the pursuit of health. We can only trust however, that he will have no cause to complain of the "samples" which the clerk of the weather will provide for him.

Mouth Breathing and Cycling.

A NOT inconsiderable proportion of people are victims of a degree of nasal obstruction sufficient to render it necessary to use the mouth more or less for breathing purposes. In an even larger proportion the obstruction allows of sufficient air being inhaled during comparative repose, but muscular exertion, or emotion, obliges them to supplement nasal respiration by opening the mouth. If one takes the trouble to look at the cyclists who pass, from this point of view, some surprise will be caused by the very small number among them who can ride at from seven to ten miles an hour without breathing through the mouth. This relative obstruction is a serious thing, because it deprives the cyclist of a great safeguard just when circumstances render the safeguard more than ever desirable. Whether in the crowded thoroughfares of large towns or in the wind-whipped roads and lanes of the country, dust is always present, usually in very uncomfortable quantities. It "blisters" the eyes, irritates the delicate mucous membrane of the nose, and, if inhaled as the result of breathing through the mouth, a tangible quantity must inevitably find its way into the bronchi, and even into the finer ramifications of the pulmonary air passages. The inability to carry on respiration

through the nose should be regarded as a positive disqualification for cycle riding, for there can be no doubt of the injurious results of inhaling the flinty and often microbe-laden dust which the cyclist has to meet, unless, indeed, mouth breathers would consent to wear respirators. It must be admitted that a respirator, however artistically constructed, can never be made a thing of beauty, but it would match very well the goggles which many cyclists wisely wear when touring, and after all, immunity from pulmonary disease would be cheaply purchased at the price of sacrificing the modicum of beauty to which a begoggled and travel-stained cyclist can lay claim.

The Transplantation of the Human Ovary. In a recent number of the New York Medical News a case is reported in which a woman, æt. 39, suffering from the effects of an artificially-induced menopause in a severe form, was greatly relieved and menstruation re-established, by the introduction through the vagina into the peritoneal cavity, of a healthy ovary removed from a young woman who had no further use for the same. Not only did the menstrual flow reassert itself but sexual desire was re-established, at least so the patient stated. We are unable to imitate our contemporary, the Medical Record, in commenting seriously upon the case, nor can we commend the operation for imitation. leave a little bit of healthy ovarian tissue, when this is possible, is doubtless a good instance of conservative surgery, but to insinuate a whole ovary, belonging to another woman, into the peritoneal cavity is hardly a procedure which commends itself to one's surgical instincts, and is likely to set up serious mischief. The operation, indeed, may be placed on a par with another recently recorded surgical feat, that of removal of the entire stomach. It may be brilliant surgery, but from a therapeutical point of view of doubtful value.

Pinchbeck Titles.

THERE seems to be a swelling craze nowadays for the possession of some qualification or other which will enable the owner to print some letters at the end of his name. We do not speak of the official degrees and diplomas which allow a man to style himself M.D., or M.A., or L.S.A., or D.C.L., and so on. Nor, again, do we mean certain honorary distinctions such as the F.R.S., of which any man may be justly proud. So, too, may a distinguished traveller or explorer be justified in adding F.R.G.S. to his cognomen, but the distinction loses its significance when we see it appended to some obscure Smith or Brown, who has never been outside his native country, and whose knowledge of geographical science is of the scantiest. As a matter of fact, his right to the magic letters is bought by his entrance fee and subscription to a learned society, just as sure as the F.Z.S., F.R.H.S., F.R.Z.S., and others are often obtained. It is not the use of these descriptive titles, but the abuse of them which we criticise. The inherent snobbery of mankind is nowhere more painfully apparent than

in the flourishing trade that has been carried on of late years by big sham learned societies that confer the privilege of a string of letters upon their members. Even Christian Science, latest of medical quackeries, is in the field with C.S., which reminds one in some way of the unqualified practitioner who signed himself M.S., and excused himself on the ground that he was a medical student. Clearly, any self-respecting, learned society should discourage the use of unrecognised or pinchbeck titles by its members.

Small-pox in London.

THE first death from small-pox in the whole of London has just been announced by the Registrar-General. It occurred on the hospital ship Castalia, and the unfortunate victim was a man of 32, who had been removed from the West-end. Deceased had been vaccinated, a fact which may afford some satisfaction to the anti-vaccinationist party, who are not apt to hesitate over such trifles as the fallacy of small numbers. A hard nut for them to crack, however, will be the decrease of a malady that formerly was as rife as measles to a point approaching zero. Last year there was only one death in the Metropolis from this loathsome disease, and during the first six months of the present year there Look upon this picture has been one more. and upon that. That isolation and improved methods of treatment and better standards of life have had a good deal of influence upon the result, few medical men will be inclined to doubt. On the other hand, the vast majority of the profession will assuredly attribute the lion's share of the glory to vaccination. Other communicable diseases, such as scarlet fever and typhoid fever, although submitted to similar preventive conditions, have not decreased in anything like the same ratio as small-pox. Let us ask this question of the anti-vaccinationists. If improved environment account for the decrease of small-pox. why has it not similarly scotched the plagues of scarlatina, summer diarrhea, and enteric fever, to which the bettering of external conditions has been equally applied?

The Election at the College of Surgeons, England.

The candidates who have come forward for re-election and election to the Council at the Royal College of Surgeons, England, consist of Mr. Jessop, of Leeds, Dr. Ward Cousins, of Southsea, President-elect of the British Medical Association, Mr. Herbert Page, of St. Mary's Hospital, Paddington, and Mr. Jordan Lloyd, of Birmingham. Of the two latter Mr. Page has on two or three occasions unsuccessfully sought the suffrages of the Fellows, while Mr. Lloyd makes a plunge for the distinction for the first time. A notable feature of the election is that three provincial Fellows will compete for two vacancies. Their colleagues, therefore, will have ample opportunity of supporting the provincial representation.

A Post-Graduate Course of Balneology. MEDICAL men who are just now occupying their thoughts with the disposal of their approaching holidays, may be glad to know of an annual excursion which combines the pursuit of pleasure with the acquisition of useful knowledge. For some years past a scheme has been carried into execution for the purpose of enabling French practitioners to become personally acquainted with the principal French watering places and health resorts. Early in September a rendezvous is given to those who have taken the precaution to inscribe their pames beforehand at some town, conveniently situated in view of the programme, and thence the members are conducted under the guidance of a selected medical authority to the best known resorts. This year the excursion, which is open to all qualified practitioners irrespective of nationality, is to be under the guidance of Professor Landouzy, who will inaugurate the tournee at Montlucon on September 2nd. Members will be taken among other places, to La Bourboule, Mont Dore, Vichy, and St. Honoré, winding up at the end of an eleven days circular trip by a visit to Pougues. Special arrangements are made for the transport and reception of the visitors, who are conducted franco for a sum not exceeding £8 (200 francs), which includes all expenses from the point de depart to Pougues. This affords an unequalled opportunity of visiting the most picturesque and interesting parts of France; and as members are allowed to bring along their lady relatives, if so minded, nothing is lacking to make up a very enjoyable trip. Adhesions are received up to August 15th by Dr. Carron de la Carrière, 2, Rue Lincoln, Paris, who will be pleased to give all information concerning the excursion.

The Eradication of Tuberculosis.

WE publish elsewhere a paper on the subject now very much à la mode, viz., the eradication of tubercu-Though it is but quite recently that the possibility of circumventing this disease has been taken into serious consideration, the practicability, by concerted measures, of eradicating it from our midst, is one which the author of that paper has for many years been an ardent advocate, and this too at a time when it was regarded as a sort of wild-cat scheme unworthy of attention. It must be some satisfaction to Dr. Fleming to see his pet scheme gradually coming to the front with a less remote prospect of a co-ordinated attempt being made to carry it into effect. The eradication of the disease is really a far more important subject than its curative treatment, for the latter deals with individuals while the other concerns countless thousands of possible victims. It will be some time yet before public opinion has been sufficiently educated to override vested interests and to make the necessary sacrifices of time and money. We possess to a great extent the required knowledge, but nothing can be done on any considerable scale without the hearty sanction and support of public opinion, and Dr.

Fleming may claim a share of the credit due to those who have persistently striven to spread a knowledge of the factors with which we have to deal.

The Physiological Effects of Castration in the Male and Female.

A GREAT deal of speculation has found expression in contributions to the study of the physiological effects of castration in the male and female, but, in truth, it is fundamentally erroneous to treat the two operations as if they had anything in common. The ovary is not a gland like the testis, and it is hardly likely therefore that the former possesses any internal secretion akin to that which is held to be furnished by the testis. The loss of this internal secretion in the male is credited with the production of more or less marked depression, which not unfrequently culminates in melancholia. In the female, on the other hand, the functions of the ovaries which call for removal have generally long since fallen into abeyance so that the ablation of functionally inactive organs is not likely to entail any corresponding constitutional disturbance. With regard to the sexual appetite, its preservation or otherwise must greatly depend upon circumstances. The loss of the ovaries in an unmarried female usually leaves the sexual appetite undeveloped, whereas in a married woman the nervous system has received previous impressions which may keep awake and prolong the period of sexual activity. The same thing holds good in males. If the testicles are removed before puberty no sexual appetite is developed, but if what we may call the sexual habit has been formed the nervous system reacts to certain stimuli as a matter of routine even though the original essential stimulus is wanting. After all, these are details of no practical importance, because the conditions which call for castration on the one hand and removal of the ovaries on the other are always such as to render the question of sexual appetite a point of more than secondary importance

A Lady Resident Medical Superintendent of a Lunatic Asylum.

A NEW departure in asylum administration was initiated last week at a meeting of the Governors of the Armagh District Asylum, when four applications were received for the position of assistant medical Only two of these personally superintendent. attended, namely, Dr. Thompson, Cookstown, and a lady, Dr. Dora Allman. The latter, on being questioned by the members of the board, said she had been an assistant in the Mullingar Asylum for over four years, where the number of patients exceeded 800. After hearing the testimonials, the board decided to appoint the lady applicant for three months. and if found satisfactory at the end of that period to make her appointment permanent.

THE honour of "special promotion" has been gazetted of O. W. Andrews, M.B., and W. J. Maillard V.C., M.D., to the rank of Staff-Surgeon in her Majesty's Fleet.

Munificent Bequests to Dublin Charities.

THE three executors-Sir William Findlater, Mr. J. Merry, and Mr. Robert Bell-to whom the late Mr. James Weir confided the charitable disposition of his large fortune, have made their award, with the result that thirty-four of the Dublin charities divide among them £100.800. Ten of these were not strictly medical institutions, and before any portion of the bequest could be awarded to them it became necessary to apply to the Court of Chancery to define the word "hospital" in the will. Already ten of the institutions benefited have received £1,000 each, but as £90,800 still remains in hand it is probable that these grants will be supplemented. We may epitomise the list by saying that it includes—(1) Twelve of the recognised Clinical Hospitals of the City: (2) the three Maternity Hospitals; (3) the Victoria Eye and Ear Hospital; (4) Cork Street Fever Hospital; (5) the two Children's Hospitals; (6) the two Convalescent Homes; (7) the Hospital for Incurables and twelve other miscellaneous institutions. The total sum left by Mr. Weir at his death was £200,800 of which £100,000 went to his relatives. He began life sixty-five years ago as assistant in a grocer's shop, afterwards became the proprietor of one of the best known public houses in Ireland, and died at the patriarchal age of ninety-two.

The Baby Incubator Again!

In commenting some weeks since on the death of a baby in an incubator on show at the Crystal Palace, we expressed our surprise that any respectable board of managers should admit an exhibit which is so manifestly unsuited for public inspection. To our surprise we find that a similar show is open to the public at the Greater Britain Exhibition, at Earl's Court, where, alongside of Savage South Africa, and various panoramas and other attractions is an exhibit of a certain incubator in which weak and prematurely-born babes are stated to be incubated under the superintendence of a competent staff of trained nurses and medical officers, ready to explain and demonstrate the use of this "marvellous scientific and humanitarian novelty." The exhibit can at most have a succés de curiosite with the public for baby incubators are never likely to become a stock article of household furniture, indeed, their value is altogether questionable.

Coming Congresses.

THE season for the foregathering of scientists is about to arrive. The first on the list is, we believe, the "International Otological Congress," which meets in London under the presidency of Dr. Urban Pritchard from August 8th to 12th. The" British Association for the Advancement of Science" will meet at Dover in September under the presidency of Sir Michael Foster. The "British Medical Association " will assemble at Portsmouth from the 1st to the 4th of August under the presidency of Sir Grainger Stewart.

'Royal Institute of Public Health" will be held in

Blackpool from September 21st to September 26th, under the presidency of the Marquis of Lorne. Lastly, "the Sanitary Institute" will hold its eighteenth congress at Southampton from August 29th to September 2nd, under the presidency of Sir W. H. Preece, K.C.B,

Scotland.

FROM OUR OWN CORRESPONDENT.

PROFESSOR SCHAFER OF EDINBURGH UNIVERSITY.-The University of Edinburgh has robbed Cambridge of her Jodrell Professor of Physiology, in the person of Edward Albert Schafer, M.B.C.S. Eng., LL.D. Aber., F.R.S. On Friday last, after a long period of excogitation on their part, the Curators of the University, in whose hands the power of election lay, proceeded to act on the opinions as to the merits of the various candidates which they had arrived at as the result of their meditations, electing Professor Schafer to the Chair of the Institutes of Medicine, so long and ably filled by the late William Rutherford.

The public notices of the appointment state that it was the result of an unanimous vote, but that, of course, but applies to the final stage in the proceedings, and we believe that it was really a very narrow majority which had previously determined what the final result was to be. Edinburgh University has got a new recruit with a very high reputation to live up to and maintain. The methods of teaching and the management of large numbers of students in one class are somewhat different in the North than South of the Tweed, but there is every prospect of Edinburgh's new professor adding more lustre to the Auld Toun's College than it has even at present, of the students of medicine acquiring a sound knowledge of physiological laws and processes, and of an important addition being made to the tale of work, already of by no means an inconsiderable magnitude and value, achieved by the Edinburgh School.

ELECTION TACTICS.—A matter which has interested many and which is connected with the recent contest for the Chair of Physiology in Edinburgh University, relates the Chair of Physiology in Edinburgh University, relates to the propriety of candidates allowing, that is the mildest term applicable, or if previously completely ignorant of what was proposed to be done of their publicly dissociating themselves from it, the publication in lay papers, or journals devoted to science apart from medicine of partisan puffs in which one candidate is described to be all that is good, his name being given, the other candidates by inference from the absence of individual notice and names being far beneath his level. But such parabeing far beneath his level. But such parareprehensible favoured candidate is credited with knowledge of and experience in subjects commented. when experience in subjects connected with the duties of the post he is contesting, of which all the other candidates are said to be ignorant, because, forsooth, the writer happens to know that this is the case in one instance. and not having heard concludes that it is absent in the rest. It is hardly possible to believe that such communications can appear with the consent and approval of a candidate, and it is almost more surprising that editors of non-medical papers should admit questionable puffs of the kind through which the opinion of the public is directed towards one man, the reluctance and proper feelings of the others preventing them from exposing the one-sided, and by omissions, scarcely accurate statements made.

APPOINTMENT OF MR. LEITH TO MASON'S COLLEGE. We understand that Mr. R. F. C. Leith, M.B., C.M., M.A., B.Sc., F.R.C.P.Ed., one of the Assistant Physicians at the Edinburgh Royal Infirmary, Lecturer on Pathology in the Extra-mural Medical School, and until

honours, and more than one valuable scholarship. He has published a large number of papers upon pathological subjects, chiefly in connection with his post as pathologist to the Edinburgh Infirmary; a volume entitled "Outlines of Lectures on General Pathology," and has contributed articles to the system of medicine edited by Dr. Crifford Allbutt. His appointment will occasion a fresh vacancy in the ranks of the assistant physicians of the infirmary, the third within the last two years.

Manchester

[FROM OUR OWN CORRESPONDENT.]

THE FUTURE OF THE ROYAL INFIRMARY.-A further stage has been reached in the negotiations respecting the reconstitution of the Royal Infirmary. At a conference recently held between representatives of the Manchester Corporation and the Royal Infirmary, with regard to the proposed purchase of the Infirmary site the Lord Mayor intimated what the City Fathers would probably be prepared to pay to the hospital trustees. It is suggested that £400,000 should be taken as the valuation of the present site; the Corporation to pay £250,000, start a fund for £100,000, to be called the Manchester Infirmary Out-Patients' Accident Endowment Fund, paying half in twenty annual payments of £2,500, the other half to be raised by public subscription; and provide the town centre with premises not to exceed £50,000. The Corporation also strongly urge that the new infirmary be built on the Stanley Grove estate, which was given to Owens College for hospital purposes. It is said that if this scheme is accepted, the infirmary trustees would he able to have perfect hospital accommodation provided without trenching upon their capital of £375.000.

HOSPITAL APPOINTMENTS. - Numerous changes are taking place in the constitution of several of the hospital The appointment of assistant physician and ophthalmic surgeon to the Royal Infirmary is to be made in a few days; Dr. Eugene Young has been elected to the post rendered vacant at the Consumptive Hospital by Dr. Milligan's resignation; Mr. Montgomery succeeds Mr. Joseph Collier as the visiting surgeon to the Union Hospital at Crumpsall; and Mr. J. W. Smith has been elected visiting surgeon to the workhouse infirmary at Withington. Further alterations are expected before long.

TUBERCULOSIS.—Manchester has long occupied a pioneer position in relation to the prevention of tuber-

culosis. Attempts have recently been made to arrange for notification of cases. It is said that there are a thousand deaths a year from phthisis in the city, and that at present there are three or four thousand cases. It has been proposed that a medical man shall be appointed as a special in-spector for this class of case, at an annual stipend of and that at present there are three thousand cases. It has been proposed £200. Much opposition was raised in the City Council. The Sanitary Committee have been directed to reconsider the whole matter. It is evident that educational measures will be preferable to coercion, if general support is to be secured in effectually dealing with tuberculosis in human subjects. Enthusiasts are apt to delay progress through their over-zeal and lack of tact and patience.

TROPICAL DISEASES.—Manchester, situated on the Ship Canal, considers herself a port of no little importance, and in many ways is in direct communication with tropical countries. There is every reason, therefore, that the lectures now being given by Dr. Graham Steell, at the Owens College, on tropical diseases, should act as the first effort to establish a fully equipped department for the teaching and investigation of this important branch of

1 athology.

VICTORIA UNIVERSITY.—The following Owens men have had their theses accepted for the degree of M.D.:— C. A. Davies, C. R. Marshall, T. A. Rothwell, Peter

Thompson, and J. D. Windle. Professor Marshall and Mr. Thompson have been awarded gold medals, and Mr. Rothwell has received the mark of commendation.

Literature.

BARBOUR'S ANATOMY OF LABOUR. (a)

A SECOND edition of this important and classical work has been rendered necessary by the number of fresh observations made since the first edition was published in 1889. The interest taken in this form of research is strikingly shown by the fact that up to 1879 three cases only had been reported; in the following ten years reports of ten frozen sections were published, the author being responsible for three; whilst in the ten years that have elapsed since the publication of the first edition of this work there have been twenty-five cases reported. The contribution of the Edinburgh School to this result has been considerable; Barbour has examined two cases, Barbour and Webster two, and Webster four; while Lusk's case, which comes from New York, may be credited to the same school, inasmuch as he had the personal advice and assistance in his work of Clarence Webster. As might be expected in a record of facts as distinguished from theories, the present edition has involved practically no correction of the matter of the first; but new facts have been gleaned by the recent work. Accordingly, the author has left the old matter untouched, and has simply added a chapter (chapter VII.) of fifty-six pages describing the last twenty-five sections; and in the same way he has made an addendum of fifty-four pages to Part II., comprising the literature of the subject. In its way this Part II. is almost as monumental a piece of industry as the description of the frozen section itself It is not simply a bibliography, but consists of abstracts of contributions to the subject, made in the first instance for the author's own use. fewer than sixty-six contributions are thus abstracted, and this part of the work must be regarded as indispensable to anyone working on similar lines.

The "Anatomy of Labour" is not a work that appeals

solely to the anatomist or to the scientific obstetrician; it sheds important light on the actual practice of obstetrics, as will be sufficiently evident from the following summary of some of the new facts learned regarding the second stage of labour. "The shortening of the anteroposterior diameter of the bony pelvis by the soft parts is for the conjugate, at the brim half an inch, in the cavity three-quarters of an inch, at the outlet seven-eighths of an inch; and for the oblique diameter, at the brim almost one inch, and in the cavity still more, due to the projection of the obturator internus. The peritoneum is, during the second stage, lifted out of the pelvis anteriorly and somewhat elevated posteriorly.

. . . The lower portion of the anterior uterine wall is thinner than the rest before labour begins; this thinning is increased during labour. A corresponding thin part develops posteriorly. There is, therefore, in normal labour (that is, with no pathological resistance) a separation of the uterine wall into two parts at the retraction ring. While the anterior vaginal wall retains, during labour, its usual length and thickness (2 ins.) the posterior stretches to more than twice its former length (measuring 7 ins.), and becomes very thin. The flexion of the head becomes, during labour, less pronounced than it was during pregnancy. Rotation of the head takes place before that of the shoulders, and is therefore inde-pendent of it. The placents does not become separated, as a result of the diminution of its site during the second stage. The membranes become separated, during the second stage, up to the retraction ring, but not above it." The author never loses sight of the bearing of science on practice; and, accordingly, we find paragraphs dealing in a suggestive way with the question of the management of labour, both in the second and in the third stage. As space will not allow more quotations, we must

⁽a) "The Anatomy of Labour as Studied in Frozen Sections."
By A. H. F. Barbour, M.A., B.Sc., M.D., &c., Assistant Physician
for Diseases of Women to the Royal Infirmary, Edinburgh. Edinburgh: W. &A. K. Johnston, 1899. Second Edition. 262 pp. 6e.

refer the reader to the book itself. All the illustrations are good, and many of them must be described as excel-lent. We would gladly see the work in the hands, not only of the specialist and the teacher, but also of the student and the general practitioner. The plea that sound scientific knowledge makes good and successful practice needs no advocate at the present day.

DAWSON WILLIAMS ON DISEASES OF CHILDREN. (a)

This book affords a thoroughly sound survey of the important branch of medical work with which it is concerned. In no instance is necessary detail sacrificed to conciseness, while at the same time the more general groundwork is given its proper place. For instance, the statistics of tuberculosis, a subject of supreme interest as regards children, are discussed fully enough to bring out the chief facts as to age incidence. The author's table shows that "the extreme liability to tuborculosis during the first two years of life, and, since children under six months are very little subject to the disease, it indicates a rapid increase during the second six months of life." The clear practical description of tuberculosis which follows serves to emphasise the hopeless nature of the prognosis when once the diagnosis is established. The enormous number of infantile deaths due to tuberculosis warrants the physician in devoting the most painstaking labour to the investigation of the subject, and this is what the author has done. It is not his part to enter into the field of prevention, wherein lies the hope of future generations. Dr. Williams avails himself freely of illustrations to portray types of disease. The frontispiece, for instance, shows the characteristic attitude of a baby suffering from posterior basal meningitis. We venture to su mise that a few minutes stuuy of that plate would convey to the mind of the practitioner a picture that would be indelible. Not only that, but he would also carry away with him the lesson as to the rallying power of infants labouring under that distressing disease after reading the note that "the patient recovered sufficiently to leave the hospital." There is an excellent X-ray photograph of the curving of the bones of the leg in rickets, and in future editions we shall doubtless be favoured with further Röntgen illustrations, which are specially available in the case of children. This volume may be recommended alike to the general practitioner and to those who are specially interested in the study of pediatrics.

JESSOP ON DISEASES OF THE EYE. (b)

THE tasteful colour of the binding of this book-by which the volume would add lustre to a drawing-room table—to say nothing of its convenient size, excellent print, and general "get up" prepossess us in its favour, even before proceeding to peruse its contents, and causes us almost to forget that it forms another contribution to the already over loaded list, as we think, of text-books upon ophthalmic surgery. With its raison d'etre, however we have nothing to do; that is a matter which concerns the author and publisher. So far as the former is concerned, he says in the preface that, in writing the manual, his "endeavour has been to make it systematic, practical, concise, and at the same time comprehensive," and on perusing his pages we are glad to admit that he has thoroughly succeeded in his task: The practical nature of the work is eminently shown by the first three chapters being entirely devoted to the methods of examining the eye, in which is given precisely the kind of information of which a student is most in need when beginning the subject of ophthalmology. Again, instead of entering largely upon the

description of the anatomy of the eye, a short and useful account of the anatomy of the various structures of the organ heads the chapters in which the subject of their diseases is discussed. This arrangement has much to commend it, and is a vast improvement upon the older method of dealing at great length with the anatomy and physiology of the eye in two or more exhaustive chapters So far as the practical part of the volume is concerned the chapters are obviously largely compiled from the author's own experience, and the views expressed, especially as to treatment, are clearly a reflex thereof. We do not at all times agree with the author-differences of opinion must always exist in matters of practice—nevertheless, we have no hesitation in saying that he has produced a sound and practical guide to the subject of ophthalmology. For the most part the illustrations are good, and the same may be said of the few coloured plates representing certain normal and pathological conditions. ditions of the fundus. It is curious, however to note the absence of the central light streak on the retinal veins in the coloured plates. A useful chapter is added descriptive of eye symptoms and diseases in general diseases, and in an appendix such matters are discussed as formulæ, general rules for operating, lenses, spectacles, &c., and the regulations for vision testing of candidates for the Government services. Altogether we can cordially recommend this book to the student and practitioner.

LUFF'S PATHOLOGY AND IRFATMENT OF GOUT. (a)

This book is a continuation and extension of the Goulstonian Lectures of 1897 on the Chemistry and Pathology of Gout. The author considers that the influence of many things on the development of gout is in great part due to the effect they exercise in the metabolism of the liver, and the increased amount of glycocine that passes on to the kidneys, which glycocine causes an increased production of uric acid by the kidneys.

The author has shown experimentally that the alkalinity of the blood is not appreciably diminished during a gouty attack; and that the solubility of sodiem biurate is markedly increased by the presence of the mineral constituents of most vegetables, but diminished by the mineral constituents of meat. Practitioners will find the book suggestive and helpful when arranging the dietary and medication of their ratients.

CLELAND'S DISSECTIONS. (b)

THE fourth edition of this work, now before us, is from the pen of the learned Professor of Anatomy in the University of Glasgow, and from that of Dr. MacKay, a former pupil and assistant. Speaking generally, the small work is of great excellence, and could only have been written by a master or masters, in the art of dissection.

It is intended as a dissecting-room guide for students, who use the large work on "Human Anatomy" by the same authors, for the acquisition of their detailed knowledge in their evenings at home; this purpose being facilitated in this edition, by reference to the page or pages of the large work, in which the detailed description of the structures which the student has laid bare during the day is dealt with.

The authors, in their short summary, allot more of the back to the dissector of the upper limb than is customary in the generality of schools, allowing him the erector spine from the level of the spinous process of the axis, as well as the spinal canal and the spinal cord, although the latter, it is mentioned (page 18), is only to be opened by the senior dissector; one wonders what becomes of it in the case of the junior, as no instruction is given to the dissector of the head and neck that in the latter case he may proceed. In our judgment the general custom is the better one of allotting to the dissector of the head and neck, the whole of the

⁽a) "Medical Diseases of Infancy and Childhood." Dawson Williams, M.D., Physician to East London Hospital for Children, &c. Cassell and Co., London and New York. 1898.

(b) "Manual of Ophthalmic Surgery and Medicine." By Walter H. H Jessop, M.A., M.B.Cantab., F.R.C.S.Eng, Ophthalmic Surgeon to, and Lecturer on Ophthalmic Medicine and Surgery at, St. Bartholomew's Hospital; Consulting Ophthalmic Surgeon to the Paddington Green Children's Hospital. London: J. and A. Churchill. 1898.

⁽a) "Gout—its Pathology and Treatment." By Arthur P. Luf, M.D.Lond., F.R.C.P. London: Cassell and Co. 1898. Pp. viii-248. (b) "Directory for Dissection of the Human Body." By Profs. Cleland and MacKay. Glasgow: Jas. Maclehose and Sons. Fourth Edition. Pp. 196. Price 3s. 6d. net.

erector spine muscle, with the spinal canal and its contents, as he thus receives the entire central nervous system at one allotment, leaving to the dissector of the upper limb what of the back more naturally belongs to him—the latissimus dorsi, the rhomboids (perhaps the two serrati.) and his share of the trapezius, and the levator

anguli scapulæ.

If this is done it is the dissector of the upper limbs who loses the two last days of the four on which the subject lies on its face, and not the dissector of the head and neck, page 80. Should the summary of this part of the back be transferred from the upper limb to the head and neck, it would be an improvement, although there may be also two sides to this question. The originality and independence of the authors in regard to current fashionable description, is exhibited in their remarks respecting the pelvic fascia, page 190, a feature much to be admired, and one very evident on every page of this small work. The book can be cordially recommended to every student of anatomy.

Literary Aotes and Gossip.

MR. JACKSON CLARKE, F.R.C.S., has a work in the press on "Orthopædic Surgery," which will include the advances made by radiography in this department of surgery.

Dr. David Walsh has a new edition of his "Röntgen Rays in Medical and Surgical Work" in the press, which will contain the latest experiments and appliances in this new science, together with illustrations of its practical experiments.

The third edition of Sir Wm. Broadbent's "Diseases of the Heart" is, we are informed by the publishers, Messrs. Baillière, Tindall and Cox, almost through the press, and is expected to be ready for publication in a few days.

THE new "Manual of Surgical Treatment," by Mr. Watson Cheyne, Professor of Surgery in King's College, London, of which Part I. was issued a few days ago, will be completed in six parts, forming a comprehensive work of reference.

Messes. Wright and Co., of Bristol, are about to issue a "Synoptical Index" to drugs and treatment for the twelve years 1887-1898, during which the Medical Annual has been published, forming, as it were, a key and complete index to the twelve volumes.

Messes. Longmans & Co. announce that the new edition of the late Professor Coats' Manual of Pathology" will not be ready until the early autumn. Dr. Lewis Sutherland, assistant to the Professor of Pathology in Glasgow University, is engaged on the revision.

MESSES. MACMILLAN and Co., announce for early publication, in their list of Manuals of Medicine and Surgery, a new volume on "Differential Diagnosis in Medicine,' by Dr. Fred. J. Smith, of the London Hospital. The work will range widely over medical diagnosis, and is chiefly intended for senior students

By a letter in our correspondence columns, it will be seen that Dr. Wolfe, late of Glasgow, now of Melbourne, author of the weil-known manual of "Diseases and Injuries of the Eye," is now in Leipzig, where, we understand, he is spending his vacation in order to gather materials from Continental hospitals for another edition of his work.

Our Manchester correspondent informs us that several works have recently appeared, or will shortly be issued by Manchester men. Dr. Williamson has just published a small monograph on "Syphilitic Diseases of the Spinal Cord"; Dr. Kelynack has completed a manual of "Practical Pathology for Students;" Dr. Moore has translated Rieder's work on "Urinary Sediments."

In "Vitality." by Tierring Translated Rieder's Work on "Urinary Sediments."

In "Vitality," by Lionel J. Beale, M.D., F.R.S. (London: J. & A. Churchill), to hand, the author does not agree with the confidence of those who urge that purely physical and chemical actions ought to be

accepted as the true explanation of any form of life; nor does he agree with Herbert Spencer that there is community of nature between growth, as it occurs in everything that lives, and inorganic growth. There is much going over of old ground, but the pamphlet is written by an able thinker and observer.

Mr. Hime's little monograph, on "Schoolboys' Special Immorality," is evidently written by one who is convinced of the prevalence of the practices referred to and of the pessibility of eliminating them to a great extent fr m school life by suitable moral instruction and proper surveillance. It is an eloquent appeal to schoolmasters and others not to continue to ignore these disagreeable facts, but to cope with and to overcome them. Every credit is due to Mr. Hime for having boldly tackled a repulsive subject, and for having handled it firmly but with delicacy. The essay will be read with interest by others than schoolmasters, but many of the latter may find his practical hints usefully suggestive.

"The Living Substance," by Gwedolen Foulke Andrews (Boston: Ginn, and Co.), is an attempt to teach us more of protoplasm than we have yet learned, and certainly on the face of it one would think we should now get nearer the truth of what Huxley terms the physical basis of life; but if there is more light here it is shaded by a rather strained literary effort which spoils the scientific effect. The descriptions are by no means so intelligible as one would desire, and it is difficult to know sometimes where Bütschli ends and the author begins. As regards the visible protoplasmic structure the evidence seems to be very much the evidence of Bütschli. What is wanted here very much is illustration. There is none, and though one feels that the author has done a large amount of work, microscopic and otherwise, she has not done herself full justice in bringing it to light.

In "King's American Dispensatory" (the Ohio Valley Co.. publishers, Cincinnati) we have a book somewhat on the lines of the "Reference Book of Practical Therapeutics," in two volumes, edited by Dr. F. P. Foster. It is certainly a very remarkable work of reference, and is issued in the best American style. It seems to be extremely accurate and comprehensive, and is quite up to date It is singular that works of this description, for some reason or another, command a much larger sale in the United States than they do in this country. It is well written and well illustrated, and may fairly be described as a monumental work. It is certainly marvellous that anyone could be found with the time, energy, and ability to compile a work of this description, and the greatest possible credit is due to the authors, Drs Felter and Lloyd, and, we may add, to the publishers. We wish them every success in their venture.

THE "Golden Rules Series" (John Wright and Co. Bristol), inaugurated by Mr. Hurry Fenwick's popular little compilation, "Golden Rules of Surgical Practice," has been enriched by a similar series of "Don'ts" and "Do's" in Gynæcology by Dr. S. Jervois Aarons, and in Obstetrics by Dr. W. E. Fothergill, and by Golden Rules of Medical Practice by Dr. Arthur Hy. Evans. Mr. Fenwick's aphorisms are well chosen, and for the most part very apt and to the point. More than one practitioner during the last year or two would have fared better had he grasped such an axiom as the following:-" Never forget that the surgeon who neglects to suture a divided nerve or tendon commits the same mistake as he who neglects to reduce a fracture." Gynecology does not lend itself to this process of treatment as readily as a wide subject like surgery, consequently many of the injunctions and (may we call them?) disjunctions do not carry conviction to the same extent. Nevertheless there are plenty of things in gynæcology as elsewhere which "were better left undone," and to these interalia Dr. Aarons has directed atten-tion. Dr. Fothergill's "Golden Rules of Obstetric Practice" are in reality a series of hints as to what to do and what not to do under given circumstances, in fact, a sort of " practical cram book."

Obituary.

MR. LAWSON TAIT, F.R.C.S.

With the death of Mr. Lawson Tait, Great Britain has been deprived of the most original surgeon she has produced in the last quarter of a century, and the whole world of surgery has to deplore the loss of one of the most gifted masters of the art. His was one of those exceptional minds that mark an epoch in the history of any science or art in which they occur. They are altogether out of the common, and for this very reason are often incapable of being understood by men of ordinary, or even above the ordinary, mental calibre. It is not in the light of what we designate clever and able minds that we regard such. We are forced to recognise in them gifts and powers entirely apart from those that are acquired by education, training, and experience. It is not with these that the "infinite capacity for taking pains" explains the brilliancy and originality of their work, though it may enable them to develop and place it on a substantial basis. It is rather that subtle quality of

brain in which conception and imagination play the greater part, and which, when allied to that other quality, audacity, which has been taken as another reading for genius, give to the world and humanity their greatest gains. Lawson Tait combined in vary ing degree all these qualities. Laborious and painstaking in his work. strikingly original in the ideas which gave it shape, characteristically audacious in carrying these ideas into operation and impressing them upon a too reluctant and unbelieving profession, he could not, and never did, expect to escape the jealous carpings. the unworthy criticisms, and the specious inuendoes which contemporaries, with no claim to his powers as a surgeon, or to his manipulative resources as an operator. were wont to aim at him. He has passed away, still a comparatively young man, at the age of fifty-four, having been born in Edinburgh in the year 1845. He was the son of Archibald Camp-

bell Tait, a Guild brother of Heriot's Hospital, to which school Lawson Tait was admitted at the age of seven, remaining there until, gaining a scholarship, he entered Edinburgh University. From 1860 to 1866 he was engaged in his professional studie-, and was under the guidance of an able surgeon, M'Kenzie Edwards, a favourite pupil of Sir William Fergusson. Here also he came under the influence and teaching of Sir James. Simpson, and determined to pursue the branch of surgery that he afterwards adorned, which might be said then to have been in its infancy. In 1870 be became a Fellow of the College of Surgeons in Edinburgh, and a year later took the Fellowship of the College of Surgeons of England. After a short time spent at Wakefield as house surgeon, he went to Birmingham, selecting this town as an appropriate field for the practice of that department of surgery which he had determined to follow. At Birmingham he took an active part in the origination of the Women's Hospital, in conjunction with Dr. Savage, in which institution he afterwards achieved many of his most brilliant successes. Here he did not confine himself to the pursuit of his profession alone, for he joined

the staff of the Birmingham Morning News, then edited by Mr. George Dawson, and was appointed lecturer on Physiology and General Biology to the Midland Institute in 1871. Tait was but twenty-five years of age when he went to Birmingham, and three years before he had performed his first abdominal section. He was only twenty-eight when he obtained the Hastings Gold Medal of the British Medical Association, which was then given to him by Sir William Fergusson, who made exceptionally complimentary remarks to the young surgeon on the unusual brilliancy and originality of his essay on "Diseases of the Ovaries," an essay which, written at a time when the pathology of the uterine adnexa had made but little advance, immediately drew attention to Tait and established his reputation as a pelvic surgeon.

It is not possible in such a notice as this to refer even to the most important of the advance in gynæcology in which Lawson Tait took so prominent and active a part. During the latter part of the seventies his fame had still further enhanced the reputation of the Birmingham School. His writings on the physiology and pathology of

the ovaries and Fallopian tubes, on the intra-peri-toneal method in ovariotomy, on tubal feetation, and on the treatment of extra-peritoneal management of the pedicle by clamp added to his marvellous successes in ovariotomy, and abdominal surgery generally, had given him a world-wide fame. Not in pelvic surgery alone did his originality manifest itself. In 1879 his paper on "Cholecystotomy" was read before the Medico-Chirurgical Society, and appeared in its "Trans-actions." Various other original feats in abdominal surgery followed, and from different schools in America and on the Continent distinguished surgeons came to see his work and methods of operating. There was but one opinion as to his manipulative dexterity and definess of hand, celerity, boldness, and completeness were the characteristics of Tait's operations. There has been, from time to time, doubt thrown on his statistics, but there is no ground that

we know of whatever for questioning the accuracy of these. Some years since, during a painful episode of his life, when these of the Women's Hospital at Birmingham were impeached, he took immediate and unanswerable steps to verify them before the profession, and most satisfactorily did so. In his earlier cases of hysterectomy, when his mortality was very high, the disastrous results were published frankly and above board.

Tait's fame, however, most specially rests on his boldness in the treatment of diseased conditions of the adnexa by operation. Undeterred by attacks, and uninfluenced by hostile criticisms, he established the operation of cophorectomy as the surgical procedure for suppurative conditions of the ovaries and tubes in given cases of bleeding fibroma, and proved the necessity for immediate operation in ruptured tubal gestation—advances in gynæcology which were not achieved without much obloquy and unjust aspersion. He lived, however, to see the range of gynæcological surgery in these directions, and in justifiable operative procedures, pass far beyond the limits which he, in the earlier days of his advocacy, conceived that they would. With many

other matters of pelvic surgery his name is associated. As, for instance, the treatment of pelvic abscess by abdominal section and drainage, and his operation for ruptured perineum. Lawson Tait was not what can be called in the modern sense an aseptic surgeon, and he held with characteristic obstinacy of mind to older methods of operation. He ignored Listerism, and refused to be a disciple of the great English teacher of anti-septic and aseptic methods. Here, as in his advocacy of the anti-vivisectionist movement, we believe that he was mistaken, and we cannot but feel that his results, brilliant as they undoubtedly were, would have been still more so had he adopted, as is now universally done, Listerian methods. By ordinary precautions of cleanliness, in conjunction with his great dexterity, Tait's results may be explained. We do not know how far those statistics might be modified by those of all operations he performed in private practice, but this has to be remembered, that if he lost at any time directly through the neglect of aseptic precautions, the price was a dear one to pay for his rejection of Listerism. His last communication (but a few weeks ago) to The MEDICAL PRESS AND CIRCULAR, to which he has been a constant contributor for many years, and to which lately he has addressed nearly all his original communications, shows how determined and honest was his opposition to vivisection. "Some day," he said, "I shall have a tombstone put over me, and an inscription upon it. I want only one thing recorded on it, and that to the effect only one thing recorded on it, and that to the effect he laboured to divert his profession from the blundering that has resulted from the performance of experiments on the sub-human group of animal life, in the hopes that they would shed light on the aberrant physiology of the human groups." Alas! all too soon has the ruthless hand of death brought to an end a career which, at the time this was written, no one dreamed was so near to its conclusion.

Lawson Tait was an Honorary Graduate of several universities. In politics he was a staunch Liberal, and at one time thought of entering Parliament, but was defeated at the 1886 election for the Bordesley Division of Birmingham by Mr. Jesse Collings. Of late years he relinquished much of his practice, building for himself a residence at Llandudno facing the Conway estuary and the Penmaenmawr mountains, taking an active interest in the development of Llandudno, and only last month buying the Old Telegraph Inn, on the highest point of the Great Orme's Head, with a view of converting it into a sanatorium for consumptives.

Much more could be written and said of Lawson Tait, for his history has been also the history of British gyne-cology for the last twenty-five years. We have naught to say to certain personal attributes which brought him many and relentless enemies. His best friends—and he had hosts of ardent admirers - would have often wished that in debate and in medical literature his attitude in scientific discussion were other than it was. This tendency doubtless cost him the loss of the highest professional and social distinctions, but he could always feel the internal conviction that the name of Lawson Tait would pass down on the roll of the great British surgeons who by their researches and work have been the milestones which mark for us and those to come the evolution and progress of British surgery. His death came rather suddenly after previous indisposition, at his residence, St. Petroks, Llandudno. The remains were cremated at Liverpool, and the ashes have been deposited, in accordance with his own special request, in a cave in his private grounds.

MR. JAMES ARNOLD, OF SMITHFIELD.

WE learn with regret the death of Mr. James Arnold, the senior partner in the well-known firm of Surgical Instrument Manufacturers, of West Smithfield. We have been asked to state that the business will be carried on as usual by the two remaining partners, Messrs. J. E. and E. R. Arnold, sons of the deceased.

MR. HENRY MORRIS, F.R.C.S., has been re-elected a member of the Court of Examiners of the R.C.S.Eng. for a further period of five years.

Correspondence.

We do not hold ourselves responsible for the opinions of our correspondents.

ON SERUM INOCULATION.

To the Editor of THE MEDICAL PRESS AND CIECULAR. SIR,-I have just read my letter, with the appended note on the above subject, in your issue of the 31st ult. My commentator evidently does not wish to see the difference between the inoculation, for diagnosis, of ailing animals, as practised in Glasgow, and the whole-sale inoculation of the animal virus into all healthy animals for diagnostic purposes; although it had been proved by experiments, on a large scale, that of the healthy animals thus treated 146 per cent. became tuberculous the following year.

THE MEDICAL PRESS AND CIRCULAR advocates vivisection and experimentation on lower animals in the interest of the study of human physiology and pathology. Now, the lessons which vivisection and experimentation teach us are that, "The higher we rise in the scale of zoological life, the more do diseases become complicated, and surgical operations and the administration of poisons will more readily prove fatal. Thus, for instance, a surgical operation which may be borne with impunity, or a poison which may be eliminated from the system and prove harmless in the case of shepherds' dogs or horses of Brittany, will prove fatal to pointers (chiens de chasse) or to high bred horses (chevaux Anglais). Further, the same animal may escape with impunity some operations when the nervous system or the stomach happens to be in a certain condition, but will succumb when in a different state of health. The numerous experiments which you have seen me perform here upon

different animals put this proposition beyond doubt." (a)
It is, therefore, evident that when we inject an animal
virus, such as Koch's tuberculin into a number of healthy animals, some will eliminate it from the system and escape harmless, whilst in others it will form tuberculous nests for the contamination of the organism. And the higher the breed the less chance will they have to escape

contamination.

He incurs a heavy responsibility who encourages the pastoral people of Australasia to practise a system of wholesale cattle poisoning because it happens to be orthodox and fashionable to-day, but may be considered outrageous to-morrow.

I am, Sir, yours truly F. R. WOLFE, M.D., F.R.C.S.Eng. Hotel Hauffe, Leipsic, June 17th, 1899.

THE POLYCLINIC.

To the Editor of THE MEDICAL PRESS AND CIRCULAR. Sig,—It seems rather difficult to explain the reasons why the Institution just started as the Polyclinic has been created If the simple question were asked, for whose benefit is it intended, the answer, we suppose, would be — for the profession generally; at least that part of the profession that wants education. The report in the dailies of the meeting a few days ago rather leads to the impression that as the teachers are to be well paid it may not be altogether a one-sided business. Of course, the cases that attend will derive benefits, but this point is not made much of, and it rather looks as if they were to be utilised for the two other purposes above referred to. Those whose names appear as supporters of the Polyclinic are not now connected with hospitals, and it is reasonable to ask why the hospital schools should lose the aid of men of the greatest experience when the most important class of students would derive benefit from their teaching. It appears as if the hospital schools will not feel much interest in the Polyclinic, and certainly we should think that it would be well if some consideration were shown at our hospitals for those of the profession for whom the Polyclinic is intended.

It must be realised that those who have cleared them-

⁽a) From my MS. report of Claude-Bernard's "Demonstrati on Experimental Pathology" at the College de France revised pulications by the illustrious lecturer.

selves of examinations feel the want of that kind of instruction which the clinical teacher alone can give, and there is no doubt but that the Continental schools far surpass ours in the facilities they afford for high-class education. Some reform is needed in hospital teaching in London, and greater regard should be shown by those who undertake this duty of using hospital appointments less as means of advertising themselves with a view to practice than is the case at present.

I am, sir, yours truly,

L.

BACTERIOLOGY FOR VESTRYMEN.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

Sir, - It is, in a sense, comforting to learn that the organism which gives rise to consumption flourishes only in the living tissues, and promptly loses its virulence when exposed to air and sunlight, the change being due to the resulting dessication. It follows that dust from the hard high road, exposed to the blaze of the sun, when there is any, or to the drying influence of an invigorating east wind, is unlikely to contain the active bacilli of tuberculosis, for the simple reason that the moisture indispensable to their comfort and health has been withdrawn. In urban districts the local authorities take such morbid pains to supply an adequate quantity of water that the dust, highly charged with organic waste and affording consequently a very favourable evil for the cultivation of germs, is maintained in a condition well adapted for the longevity and multiplication of these germs. Local authorities do not take into account the principle that streets ought to be watered only with the object of preventing dust when they are about to be swept, unless, indeed, it be used in such quantities as to wash the streets clean. The City of London is, perhaps, the only place where this principle is recognised and applied, and local authorities in general turn a deaf ear to the wails of maimed horses and injured cyclists whose mishaps are directly attributable to the vicious plan of converting dust into greasy mud.

It lies with the Press, and especially the Medical Press,

It lies with the Press, and especially the Medical Press, to educate public opinion on this matter, and I therefore

venture to call your attention thereto.

I am, Sir, yours truly,
A Cycling Bacteriologist.

Medico-Legal Aotes.

By W. J. JOHNSTON, B.L., Dublin.

(Conclude d.)

THE MAGISTRATES AND THE VACCINATION ACT.

Every decision in connection with the Vaccination Act, 1898, is of interest, and especially every decision under the famous section which provides that no parent shall be liable to any penalty under the Act of 1867 if within four months from the birth he conscientiously believes that vaccination would be prejudicial to the health of the child. The justices of a certain district have thought it wise to adopt the rule that every applicant under this section shall produce a certificate of the child's birth. The defendants in the case of Reg. v. Loundes and others (68 L. J. R. 318) made an application to the magistrates, but refused to produce such a certificate, offering oral evidence on the point instead. The justices were obdurate and insisted on the production of the certificate. On an application to the Queen's Bench Division for a writ of mandamus to compel the Court below to hear the case, the judges held that in cases where the birth had been duly registered, it was a very proper thing to insist upon the production of a certificate, and that the magistrates were right in refusing to hear the case until the rule had been complied with.

JUSTIFICATION AS A DEFENCE IN LIBEL ACTIONS.

Three recent actions of libel, in which medical men

were the plaintiffs, illustrate in a convenient way the doctrines of the law with reference to professional character. The case of Kelly v. Colhoun and others was the simplest in point of law. The plaintiff, who was a dispensary doctor, complained of certain statements made about him at a meeting of the dispensary committee by two of the members of that committee, and these two defendants when sued for damages pleaded justification—that is, pleaded that the statements were true—which is the boldest, but at the same time the riskiest, defence that can be set up to an action for libel. The jury found that the statements were defamatory, and that they were not true, and awarded £200 damages against each of the defendants.

PRIVILEGE AS A DEFENCE.—In Forsythe v. Caldwell, the plaintiff who was medical officer of a work house, complained that a letter sent by the defendant to the Local Government Board of Ireland contained defamatory statements about his conduct as medical witness at an inquest held by the defendant as coroner in the workhouse. The defendant pleaded privilege, which is a defence available to protect all communications honestly made for the purpose of discharging some legal, moral, or social duty. It is a defence that can be rebutted only by proof of malice. The judge at the trial held that the communication made to the board in question was privileged, but the jury found that there was malice and awarded £50 damages, for which sum judgment was entered for the plaintiff.

FAIR COMMENT AS A DEFENCE.—The third case was Thompson v. Falls, in which the plaintiff, who had previously given expert medical testimony at a certain criminal trial, complained of some references made by the defendant at a public meeting) to his conduct at that trial and evidence as a medical witness. The defence was a plea of fair comment, which is one arising out of the right which the law gives everyone to criticise, fairly and honestly, every subject that is fairly open to public discussion. The jury, however, found that the defendant had gone beyond the limits of fair criticism, and gave the plaintiff £50. Of these three forms of defence—justification, privilege, and fair comment—the first is generally avoided by lawyers, and the last two, being in a way a form of pseudo apology or explanation, breaks the fall for the defendant, if a fall must come.

THE PHARMACEUTICAL SOCIETY OF IRELAND.

It is a pity that Ireland is not included within the scope of the Lord Chancellor's Pharmacy Bill. The same state of affairs exists in the sister country as in England. The Bill is intended to remedy the effect of the decision of the House of Lords in The Pharmaceutical Society v. The London Supply Association (5 A. C. 857), in which it was decided that the word "person" in the old Act did not include a body corporate, so as to make the defendants liable to the penalty under the Act. In The Pharmaceutical Society of Ireland v. Boyd and Co. (1896, 2 Ir. R. 394), the Irish Courts gave an exactly similar construction to the corresponding section of the Irish Act. But the Irish Courts have gone further. They have decided that an apprenticeship served with a limited company, carrying on business as pharmaceutical chemists under a properly qualified manager, did not entitle the candidate to be admitted to the Society's final examination when some of the members of the company were not pharmaceutical chemists. (Reg. [Cleland] v. The Pharm ceutical Society of Ireland—[1896] 2 Ir. R. 368). But in another case an apprenticeship served with a limited company, all the members of which were properly qualified pharmaceutical chemists was held to be quite sufficient. (Reg. [Conyngham] v. The Pharmsceutical Society of Ireland—[1899] 2 Ir. R., 132).

Royal College of Surgeons of England.

A MEETING of Fellows and Members of the College is to be called to consider the draft petition and charter now being prepared. Copies thereof will be supplied on application.

Laboratory Aotes.

ASEPTIC SPONGES (SQUIRE).

WE have received from Messrs. Squire and Sons, of 413, Oxford Street, W., samples of their antiseptic sponges. These consist of cotton fibre subjected to very great pressure, and we are told the "sponges" consist of discs only a twelfth of an inch in thickness. Placed in water they promptly swell up to fifteen times the original size, and are capable of absorbing twelve times their weight of fluid. They are useful for a variety of purposes, but are specially serviceable in plugging the anterior or posterior nares for the relief of epistaxis, it being possible to obtain any degree of pressure that may be required in order to arrest the hæmorrhage.

VAGINAL CAPSULES.

WE have received from the same firm specimens of their "vaginal capsules," prepared with specially soluble carbolised gelatin, serving as envelope for an absorbent tampon, which can be medicated a volunte A thread is attached to facilitate the removal of the tampon in due course. These capsules constitute a much easier and "elegant" method of introlucing medicated tampons into the vagina than the ordinary plan via a speculum, and they enable patients, when necessary, to continue the treatment themselves.

FERRO-MANGANESE PEPTONATE (SQUIRE). LYMPH OF THE GLYCERO-PHOSPHATES (SQUIRE).

CHEMICAL FOOD LOZENGES.

Among the pharmaceutical products samples which have reached us from Messrs. Squire and Son, we must mention the ferro-manganese peptonate (Squire). This fluid preparation contains 11 grains of metallic iron and grain of metallic manganese, in the form of neutral peptonised albuminates. This preparation, pharmaceutically excellent, possesses valuable therapeutic properties in that it is readily tolerated, does not constipate, and does not discolour the teeth. The average dose is a teaspoonful.

The glycerophosphates are now well in vogue, and their importance as a means of exhibiting phosphates in a soluble form is too generally recognised to require explanation. The syrup of the glycerophosphates (Squire) is a trustworthy preparation of soluble phosphates in combination with glycerine.

For the convenience of those who cannot well carry about bottles of syrup, Messrs. Squire and Sons now prepare their "Chemical Food" (Syr. Ferri Phosph. Co.) in the form of lozenges, each of which corresponds to an average dose of the syrup.

Medical Aews.

University of Dublin.

A MEETING of the Senate will be held to-day (Wednesday) to approve the following "Graces" from the Provost and Senior Fellows for the grant of Degrees

His Excellency Earl Cadogav, Lord Lieutenant of

Ireland, LL.D.

Marquess of Lansdowne, LL.D. Baron Macnaghten, LL.D.

Sir G. O. Trevelyan, LL.D. Right Hon. Joseph Chamberlain, LL.D. Professor D. P. Tiele, of Leyden, LL.D.

Professor A. R. Forsyth, of Cambridge, LL.D.

Professional Amenities.

A CASE was tried at the Lambeth County Court a few days since in which a medical witness showed himself in a rather curious light. A working man sued Mr. Shillingford, L.S.A., of Peckham, for damages, based on alleged negligent treatment f one of the plaintiff's children. The principal witress for the plaintiff was Dr. R. H. Hodgson, who, on being called in, found that the defendant had been prescribing opium, which, in

his opinion constituted improper treatment. In a letter to the defendant's solicitor he alluded to the plaintiff as "a contemptible liar." Exonerating evidence having been given by various medical men on behalf of the defendant, the jury stopped the case, and gave a verdict in favour of Mr. Shillingford.

Cambridge University.

The work of the Long Vacation Course in the Pathological department will be commenced on Thursday, July 6th, and will consist of

- 1. Lectures on General Pathology, Degeneration, Inflammation, Œdema, Shock, &c.; Special Diseases of the Circulatory System.
- 2. Demonstrations in Morbid Anatomy in the postmortem room and on formalin specimens.
- 3. Morbid Histology Degeneration, Inflammation, and Tumours; Special Diseases of the Visceral Organs.
- 4. Clinical Pathology, including examination of blood; methods of clinical bacteriological diagnosis, sputum, tubercle, diphtheritic exudations, typhoid serum test, &c.
- 5. Lectures on Bacteriology: General and Special Pathology of Infective Disease, including the production of immunity, vaccination, serum treatment, &c.
- 6. Practical Bacteriology—Methods of inoculation and staining; Practical Study of the Important Pathogenetic Micro-organisms, and Phagocytosis, Methods of Inoculation, Immunisation, &c, and the Bacteriological Analysis required for D.P.H. examination.
- 7. Should a sufficient number of students send in their names, a class will be formed for the study of the more advanced bacteriological work that cannot be included in the above course.

Mr. Strangeways Pigg (University Demonstrator) and Dr. G. H. F. Nuttall (of Berlin) will be associated with Professor Woodhead in carrying out the work of these classes. They will be assisted by a number of private demonstrators.

A syllabus of the work of, and fees for, the various classes, will be sent on application being made to Mr. Strangeways Pigg, Pathological Laboratory, New Museums, Cambridge. These classes are open to nonmembers of the University.

Tropical Diseases.

An expedition is being organised by the Liverpool School of Tropical Diseases to visit the West African coast for the purpose of investigating the causes of malaria and other tropical diseases. It is expected to start for Sjerra Leone early in August, with Major Ross as commander-in-chief. The offer made to the Colonial Nursing Association in London, to train three nurses for service in the tropics has been accepted.

Lunacy in North Wales.

According to the fiftieth annual report of the North Wales Counties Lunatic Asylum, the daily average of patients amounted to 669, as against 651 during the previous year. The percentage of recoveries was 36.56 per cent. on the admission, and the death rate 8.89 per cent.

Measles in Liverpool.

ALTHOUGH Liverpool has not suffered as much as Manchester and certain other large urban centres from the prevailing epidemic of measles, it has been judged necessary to close the infant departments of School Board and voluntary schools for a fortnight. The number of schools affected by the Order is 23.

London Hospital Medical College

THE new buildings that have recently been completed at the London Hospital Medical College will be opened on Tuesday, July 18th, by Lord Knutsford. The opening will be followed by the distribution of prizes to the students and nursing probationers in the library of the Medical College by Lord and Lady Knutsford.

COLONEL T. O'FARRELL, Principal Medical Officer of the Home District, has been appointed Principal Medical Officer at Malta.

Aotices to Correspondents, Short Letters, &c.

• CORRESPONDENTS requiring a reply in this column are particularly requested to make use of a distinctive signature or initials, and avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," &c. Much confusion will be spared by attention to this rule.

THE DOCKBELL TESTIMONIAL FUND.

OUR readers are already in possession of the facts connected with the case of Dockrell v. Dougall, in which Dr. Morgan Dockrell sought to prevent his name being used in advertisements of "Sallyco Water." His case having falled in the first instance, Dr. Dockrell decided to take it to the Appeal Court, before which he explained that the unauthorised use of his name on a circular would certainly injure his professional reputation, and also indirectly his explained that the unauthorised use of his name on a circular would certainly injure his professional reputation, and also indirectly his practice. Being unable to prove specific damage, he was again unsuccessful, the judge declining to go behind the finding of the jury. In fighting this case he was fighting the right of every man to the privacy of his own name, in doing which he has incurred legal costs to the amount of several hundred pounds, to recoup which and to evince sympathy with him on the part of the profession a Testimonial Fund has been started. The following is a list of committee and first subscription list:

Dr. R. MANDER SMITH (Ringwood).—In consequence of great resture on our space, your communication is unavoidably held over until our next.

THE INTERNATIONAL MEDICAL CONGRESS, 1900.

WE received a communication while at tress from Mr. D'Arcy Power, Hon. Sec. f r G eat Britain, informing us that the meeting of the Congress has been fixed at the busiest time of the luterna-tional Exhibition in Paris next year, rendering it necessary that all those who propose attending it should give early notice, otherwise they will not get rooms.

LAWSON TAIT. (In Memoriam).

L EFT us just in the zenith of his fame,
A leader of his branch we proudly claim,
Watchful of symptoms, ready to suggest,
S ure of his ground and anxious to contest;
O nward, his motto, not content to wait,
N eed I recall the name of Lawson Tait.

T hough gone, thou'st left a mark that shall remain A s lasting as our Science and our Art,
I mperative thou wert, thy word was plain,
T hy precept and thy practice n'er depart.

Cheltenham. ALEXANDER DUKE.

Meetings of the Societies and Tectures.

WEDNESDAY, JUNE 21st.

ROYAL METEOROLOGICAL SOCIETY (70 Victoria Street, Westminster, S.W.). 4.80 p.m. Ordinary Meeting. Papers: Mr. B. H. Scott: Heavy Falls of Main recor ed at the Observatories conne ted with the Meteorological Office, 1871-1898.—Mr. B. C. Mossman: Average Height of the Barometer in London.—Mr. J. Baxendell: A new Self-recording Anemoscope.

THURSDAY, JUNE 22nd.

CENTRAL LONDON THROAT, NOSE, AND EAR Haspital (Gray's Inn Road).—5 p.m. Dr. D. Grant: Diagnosis and Treatment of Dangerous Sequelæ of Otitis.

Bacancies.

Borough Asylum, Portsmouth.—Junior Assistant Medical Officer.

Salary, 2100, with board, lodging, and washing.

Borough of Burton-upon Trent.—Medical Officer of Health. Salary at the rate of 2350 per annum.—Applications to the Town Clerk, Burton-upon-Trent.

County Asylum, Rainhill.—Senior Assistant Medical Officer, unmarried. Salary commencing at £225 per annum, with furnished apartments, board, attendance, and washing.

Fisherton Asylum.—Assistant Medical Officer. Salary commencing £120 per annum, with board, lodging, and washing.—Apply to Dr. Finch, The Asylum, Salisbury.

Glasgow University. Assistant Examinership in Medicine, with special qualification to examine in zoology.—Applications with testimonials must be sent to A. E. Clapperton, Eq., 91 West Regent Street, Glasgow. (See Adv.)

Newport and Monmouthshire Hospital.—House Surgeon. Salary, £100 per annum, with board and residence.

Owens College, Manchester.—Senior Demonstrator in Physiology.

Stipend £150 per annum, rising to £200.

Shafteebury House Private Asylum, Formby, near Liverpool.—Junior Medical Officer. Salary, £50 per annum, with board, lodging, and washing.

Appointments.

BARKLEY, Jas., L.R.C.P., L.B.C.S.Edin., Senior House Surgeon to the Belfast Royal Victoria Hospital.

BUCK, A. H., F.R.C.S.Edin., M.R.C.S., L.R.C.P.Lond., Assistant Surgeon to the Sussex County Hospital, Brighton.

DANIEL, P. L., F.R.C.S., Surgical Registrar to the Charing Cross Hospital, London.

Hospital, London.

FISON, E. T., M.D.Cantab., F.R.C.S.Edin., M.B.C.S., L.B.C.P.,
Physician to the Salisbury Infirmary.

FOSTER, W. J.. F.B.C.S.Eng., L.R.C.P.Lond., Surgeon to the
Royal Berkshire Hospital, Reading.

FORSTER, E., M.A., House Governor and Secretary to the Wolverhampton and Staffordshire General Hospital.

HARBINSON, G. B., M.B., B.Ch. R.U.I., Junior House Surgeon to the
Belfast Royal Victoria Hospital.

LE QUESNE, C. P., L.R.C.P.Lond., M.R.C.S., Medical Officer,
Southampton Dispensary.

Births.

Cantlie.—On June 15th, at 46 Devonshire Street, Portland Place, London, W., the wife of James Cantlie, M.B., P.B.C.S., of a son. Coorg.—On June 16th, at 69 Bridge Street, Cambridge, the wife of Arthur Cooke, F.B.C.S.. of a son.

George.—On June 15th, at 1 Burton Road, Brondesbury, N.W.. the wife of Alfred W. George, M.D.Edin., M.B.C.S.Eng., L.R.C.P. Lond., of a son.

Tayloz.—On June 12th, at the Red House, Northfield, near Birmingham, the wife of John W. Taylor, F.B.C.S., of a son.

Marriages.

ATTFIELD—HERKOMER.—On June 14th, at the parish church, Bushey, Herts, Donald Harrey Attfield, M.A., M.B., son of Prof. John Attfield, F.E.S., of Watford, to Elsa Anna Iole Herkomer, elder daughter of Hubert Herkomer, R.A., of Bushey, Herts.

GIBSON—PETTIGERW.—On June 15th, at St. Peter's, Cranley Gardens, South Kensington, E. Arthur Gibson, M.D., Glusgow, to Ellen Shaw, daughter of the late Wildam Pettigrew, of Glasgow and Chislehurst

W.LLIAMS—WRIGHT.—On June 15th, at St. Andrew's Church, Woodhall Spa, Thomas Kenway Williams, M.R.C.S., L.R.C. r. Lond, of Nottingham, to Alice Mary, only daughter of the Rev. George Armitstead Wright, M.A., of Woodhall Spa, Lines.

Beaths.

Elliott.-On June 15th, at Beulah Hill, Upper Norwool, George Robinson Elliott, M.R.C.S., of Sydney, New South Wales,

REGULATER. On June 1th, suddenly, at Cove, Major Ferguson, I.M.S., second son of the late John Ferguson, M.D., M.R.C.S., Cove, Kincardine.

LANE.—On June 17th, Deputy Surgeon General, W. R. Lane, M.R.C.S. (retired), aged 65.

PARR.—On June 10th, at Upper Phillimore Place, Kensington George Charles Parr, M.D., aged 56.

Stater. On June 14th, at Northampton Hospital, of pneumonia, Leonard Slater, M.A., M.B., aged 31, fourth son of James Slater, of Bescot Hall, Walsall.

T.—On June 13th, at his residence, St. Petrock's, Llandudno West, Lawson Tait aged 54.

Original Communications.

THE ERADICATION OF TUBER-CULOSIS.

By GEORGE FLEMING, C.B., F.R.C.V.S., LL D., Late Principal Veterinary Surgeon to Her Majesty's Forces.

(Concluded from page 640.)

It was probably from the wide and intense interest taken in tuberculin as a curative agent when it was first tried, and the corresponding disappointment and regret when it failed, that gradually led to the present movement for the limitation or suppression of the disease, in view of its fatal tendency in such a large majority of cases, and the difficulties attending attempts at curative treatment. In dealing with such a malady prevention must surely be more desirable than futile and expensive curative measures.

There can be no doubt that the recognition of tuberculosis as a purely infectious disease is essential in order to establish measures for its eradication. It is solely maintained and propagated by its virulent principle or germ, and destroy that or prevent its dissemination and the disease becomes extinct. Mankind is also undoubtedly the great seed-bed of the disorder, and a diseased person may infect many scores of healthy ones before he finally succumbs; and this infection takes place all the morc certainly under circumstances which favour the rapid development of the malady and the ready dispersion of the germs. Hot, dark, damp, and badly-ventilated dwellings into which are congregated an inordinate proportion of insufficiently fed persons, are those in which tuberculosis will revel when once introduced, and the air therein becomes infective. It is so in cattle sheds, and we may presume it must be the same in human habitations. But at all times the presence of a phthisical person among those who are in any way predisposed is a source of danger unless great care is taken. Villemin was the first to suggest, early in 1870, that transmission of the malady in man probably takes place more frequently by the matter expectorated by phthisical persons becoming dried, accidentally reduced to dust, and in this form carried by the atmosphere into the lungs of healthy

The measures for the suppression of the disease in mankind, so far as its maintenance depends upon transmission from diseased to healthy persons, are sufficiently obvious. But, as we have just seen, it is not limited to the human species; it prevails extensively among cattle, and there is good reason to believe that mankind can be, and often is, infected through the flesh and milk of these animals when they are tuberculous. The question whether the disease first appeared in man and he communicated it to cattle, or whether it was originally a bovine disorder transmitted to mankind in the manner we now apprehend it is conveyed, cannot be answered satisfactorily, nor is this answer a necessity, so far as pre-ventive or suppressive measures are concerned. It is

sufficient to know that the disease is the same in both species, and that the opportunities for transmission from one to the other are numerous, seeing that the food of man is largely derived from bovines, and that these, again, are not infrequently tended by per-

sons affected with phthisis.

It is well to know that all animals are susceptible of infection. The ox tribe appears to be easily infected, so are young pigs. The horse and dog also suffer, and it was thought for a long time that the ass was immune, but is is now ascertained that he is liable to ordinary tuberculosis, as distinguished from that experimentally produced. Guinea-pigs are extremely sensitive to infection, and the disease is far from uncommon among wild animals kept in captivity, which are possibly infected by their attendants or by the food they receive, as well as by infection derived from the contaminated places in which they are confined. Even birds are not exempt, and fowls are often affected very extensively, this avian tuberculosis having been proved to be identical with the human disease, and it is probably conveyed from man to them. Parrots, dogs, and cats have become tuberculous through being kept in the same room with phthisical persons, and inhaling expectoration dust, or eating food which had been partaken of by invalids. The human being and bovines are, without doubt, instrumental in infecting other creatures, and these in their turn may infect each other, and also the species which originally infected them.

We know not to what extent man is infected from bovine or other animals, but as the disease is more or less readily transmissible from cattle to different species, experimentally and accidentally, it may be inferred that he is equally susceptible to infection from them; clinical observation affords some striking instances in support of this inference. Considering the close relationship between man and cattle, there is reason to look upon the latter with the strongest suspicion, as contributing a large share towards the prevalence of human phthisis. Scarcely any organ or tissue in the bodies of cattle is exempt from tubercle invasion; for though the diseased masses are most frequently found localised in or on the serous membranes in the chest and abdomen, and in lymphatic and other glands, yet tuberculous deposits are sometimes observed in muscle, in bone, in or on the skin, and in other situations where they

are not usually looked for.

As infection can take place by consuming flesh, it is well to know that, in all probability, this can rarely occur unless it is very much tainted, as when the animal has suffered from generalised tuberculosis, and then it can only be regarded as dangerous if im-perfectly cooked. Thorough cooking will doubtless destroy the bacilli, but as this can be seldom effected, especially with large joints, all such meat should be proscribed.

It is different with the milk from tuberculous cows. Unless boiled to such a degree that the bacilli are killed it is not safe to consume it as food, even when the udder is not involved. It must be remembered that the milk has been proved to be infective when only the lungs of the cows were tuberculous, and when no bacilli could be detected in that fluid. Consequently, to be safe, the milk from all tuberculous cows should not be allowed as food to man or beast, neither should the products from it—such as butter and cheese.

But in order to get rid of the danger of tuberculosis from cattle, as well as to suppress the disease among them, and so avert serious loss of property, welldevised sanitary measures, thoroughly and energetically carried out, are absolutely necessary, and it is equally necessary that they should be directed and controlled by a central authority. To entrust their execution to local authorities without central instruction and direction is simply losing time and giving rise to disjointed action, by which there will be caused much annoyance and expense with but little benefit. Our experience of the management of such diseases by local authorities has been of a very unsatisfactory, indeed, painful character, and there can be no valid excuse for again trusting to it. The object is to eradicate the disease from the human and bovine populations, and as it constitutes in the latter a grave scourge entailing a heavy pecuniary loss, and, besides, menaces the public health, it is surely as worthy of the attention and control of the Central Government as were foot-and-mouth disease and contagious pleuro-pneumonia, both of which were not nearly so important from a sanitary point of view, and yet on their suppression no expense or care were spared. In the extinction of bovine tuberculosis we have a great diagnostic aid in tuberculin, and the intelligent use of this will assuredly avert the wholesale slaughter of herds and inhabitants of cowsheds which so painfully marked our dealing with the two diseases just mentioned when a sick animal was discovered in their midst. We can deal with tuberculosis in a more scientific manner. Tuberculine will demonstrate the existence of the disease in an animal which appears to be in perfect health, and in which no sign of infection could be otherwise detected, one inoculation being generally sufficient, and the result known within twenty-four hours. This is an immense advantage, as it enables those who are engaged in investigating the extent of the disease in a cowshed or herd, to point out which animals are to be suspected and separated from those which do not react to the inocnlation, and to adopt the other measures required. The test is probably not altogether infallible, for in bad cases it does not give a marked reaction, but this is of little importance; as the usual symptoms are then so evident that there should be no difficulty in distinguishing the disease. In some instances animals which have given the customary reaction had been found, after being slaughtered, to be apparently free from tuberculosis; but this was, in all likelihood, because a sufficiently careful examination of the carcase was not made, as in many cases tubercle may be present in an early stage of formation, perhaps in unusual parts of the body, and so elude observation. Such cases have been reported.

In employing tuberculin, care will have to be taken to prevent fraud, especially in concealing the existence of the disease in tuberculous animals about to be sold or exported, as when once they have reacted they will not do so again for some time; so that in the interval they may be disposed of as free from the disease. Its use should therefore be restricted to those who can be depended upon to use it properly and honestly, and only with the object of diagnosing the malady.

Cattle which react to tuberculin should be segregated, and if giving milk this should not be used as food; the animals themselves, if in good condition, should be sent to the butcher, the distribution of their flesh as food depending upon the extent and character of their disease, while every precaution

should be taken with regard to cleansing and disinfection of the place they inhabited. Cleanliness, good light and ventilation, as well as good food and intelligent management of cattle are obviously necessary to preserve their health and prevent the spread of disease among them, but above all things it is essential to get rid of those which are tuberculous. This can only be effected, as has been insisted upon, by judiciously framed legislative measures carried out by the central authority of the Governments of as to ensure uniformity and efficiency.

The suppression of the disease in man renders it necessary that it should be dealt with as an infectious malady, and that sanitary and preventive measures be observed, especially in schools, workshops, and other places where numbers of people are congregated, and that sanitation be carried into dwellings which are damp, dark, and insufficiently ventilated. People who are tuberculous should be kept apart from the healthy as much as possible, and especially from young persons, and in hospitals they ought not to be admitted among patients affected with other diseases, but kept in special wards or buildings.

With regard to cattle the disorder must be included in the Contagious Diseases (Animals) Act, for surely it merits this inclusion more than any of the disorders therein enumerated; and as its suppression must entail the compulsory slaughter of badly diseased animals, it is only fair that proper compensation be given, as has been done in eradicating the other scourges comprised in that Act. That tuberculosis can be got rid of there can scarcely exist a doubt; but in order to attain this most desirable consummation the intelligent co-operation of the public must be enlisted, and especially that of the owners of cattle, whether they be breeders, feeders, or keepers of dairy stock, as they will have to submit to some inconvenience and trouble, though they will be the gainers in the end. There is no reason at all for delay in commencing operations, as everything to be known regarding the disease and the measures by which it may be successfully combated, has been in our possession for years, and if we continue to suffer from its ravages, and lament the loss of human lives that its presence entails, this must be ascribed to our own supineness and neglect. The longer we procrastinate, the greater will the loss be, and the more difficult will the task become.

A NEW METHOD OF VENTILATING SEWERS. (a)

By SIR CHARLES A. CAMERON, C.B., M.D., F.R.C.P., F.R.C.S.I., D.P.H.Camb.,

President of the Royal Institute of Public Health.

The ventilating openings in the street sewers, which are now so general in almost every town in the United Kingdom, have not met with universal approval. When first used, many complaints were made of the unpleasant odours emitted from them. The late Sir Robert Rawlinson was wont to say when such a complaint was made, "Put more ventilators in the sewer." No doubt the larger the number of ventilators the less the odours from any one of them. If they were altogether open it would be better than their present state of being open only at certain points. The houses opposite these points receive more than their due share of whatever comes out of the sewer, whereas if the sewer were as open as a ditch, every house would be treated alike to the emanations, if any, from it.

⁽a) Paper read at the Royal Institute of Architects of Ireland, May 25th, 1899.

I am bound to say that as a rule there are no sensible nuisances caused by the street sewer ventilators; but there are occasional exceptions to this rule. Now and then persons complain to the Public Health Committee that the ventilators near their houses are offensive. On examination these complaints are generally found to be justifiable. Ordinary sewage generally has very little odour until it becomes stale; but now and then what may be termed exceptional sewage, having an offensive odour, flows through sewers in our streets, and it is chiefly from such sewage that the offensive emanations come through the ventilators.

The chief object in the use of ventilators is to prevent a greater pressure of the air of the sewers than that of the external atmosphere. It is assumed that the gases generated by the fermentation of the organic matter always present in sewage might cause the sewer air to acquire sufficient pressure to force the traps on the bouse drains connected with the sewer 1 have always doubted very much that the sewer gases could acquire a pressure sufficient to dis-place two or three inches of water. I have made many experiments in reference to the so-called pressure in the air of sewers. I have had the sewer ventilators closed on considerable lengths of sewer mains, and have inserted delicate pressure gauges in them. I never observed any pressure except of the most trifling kind, in the air of the sewers when the ventilators were closed. I did, however, notice that in the early morning, air often passed into the sewers from the streets. This descent of the air into the sewer I attributed to the insuction of air from the sewer into houses, the drains of which were untrapped or provided with defective ones. the fires began to be lighted in the kitchens, air was drawn into the street sewers, especially in those parts of the City inhabited by the poorer classes. According to my experience, the pressure which occasionally may be observed in the sewers is sometimes caused by the wind. When a strong gale is blowing, gusts of wind enter the sewer through the ventilating

The second object in ventilating sewers is to protect the workmen engaged in cleaning or repairing them. I greatly doubt that the emanations from ordinary sewage are so abundant and dangerous as to imperil life or health. The manholes should, of course, be open for some time before the sewer was entered. Death of workmen from inhalation of sewer gases have not been infrequent, but it has been caused not by ordinary sewage air, but by sul-phuretted hydrogen set free from refuse from gas works, or from waste gases from gas engines allowed improperly into sewers, or from other exceptional causes.

It is worth noting in connection with the subject of this paper, that the sewers of one city, as large as Dublin, are not ventilated at all. This city is Bristol. Its sewers discharge their contents into a tidal river, in which the water rises so high that for a large portion of the day the sewage cannot escape into the river. Bristol enjoys a remarkable immunity from typhoid fever, and I am informed that no injury to the health of the workmen who cleanse the unventilated sewers has taken place.

Notwithstanding the experience of Bristol, I confess that I am in favour of the ventilation of street sewers, though not by the means now generally employed. I object to the ordinary sewer openings in streets which are narrow and confined, and I have suggested another method of ventilation, which my colleague, Mr. S. Harty, city engineer, has approved of, and uses under certain circumstances. In order to explain my system it is necessary to say a few words in reference to the passage of gases through certain solid substances. If we take a gas, say

oxygen or hydrogen, and enclose it in a vessel of metal, glass, or glazed porcelain, it will remain there for an indefinite period: but if the vessel is composed of unglazed porcelain or plaster of Paris, the gas will rapidly pass out of it. If a galvanic porous cell be connected with a glass tube, the latter filled with water, and its open end sealed in water, and a vessel of coal, or hydrogen, gas be placed over the cell, the water will be immediately expelled from the tube. This phenomenon is explained as follows:—All gases diffuse in right lines in all directions. The lighter gases diffuse more rapidly than the heavier ones, and all pass through porous materials. As coal gas is lighter than air, it passes more rapidly into the cell than the air in the cell passes out of it, and therefore pressure is caused, as shown by the expulsion of water from the tube.

I have applied this property of the diffusion of gases through porous materials to the ventilation of sewers. Cylinders, composed of a mixture of two parts of porcelain clay and one of sulphate of lime, 18 ins. in height and 6 ins. in diameter, are used. Four or six are inserted in the crown of the sewer, and in a chamber resembling that used for the ordinary ventilators. The rain that enters the chamber from the street is carried into the sewer through a small syphon, and no wet can get at the cylinders. As the cylinders allow air to pass cylinders. As the cylinders allow air to pass freely through them, but effectually bar the passage of micro-organisms, there can be no greater pressure in the sewer air than in the street atmosphere. Air continuously comes out of the sewer, filtered through the cylinders, and air as continuously enters the sewer through the porous vessel. The action of the filter on the air resembles the action of a Pasteur filter on water. The sewer diffuser ventilator is manufactured by Messrs. Doulton, of Lambeth, London, and Burslem, Staffordshire.

The "fresh air inlets" of the house drains are often the outlets for foul air. When they are placed in the basement areas of houses they not infrequently cause an unpleasant odour. a w.c. is flushed the air in the soil pipe is forced out through the inlet into the external air. Mica valves are occasionally used at the inlets to prevent the gases from the soil escaping into the atmosphere. They are never air-tight, and soon go out of order. A better protection against the emission of foul air through the inlet would be a porous plate such as is used in the diffuser ventilator. As every precaution is usually taken to prevent even a "pin-hole" in the soil pipe it seems contradictory that a large opening should be made in it. In conclusion, I may state that the sewer diffuser ventilator has given satisfaction in Dublin, and has been found efficacious. They have been in use for the last two years, and, on examination, have been found to remain quite clean.

GENERAL DISORDERS, ORIGINATING IN DISEASE OF THE FEMALE PELVIC ORGANS. (a)

> By Dr. MENDES DE LEON, of Amsterdam.

MR. PRESIDENT AND GENTLEMEN,-Although much honoured by your invitation to read a paper before this Society, it was long before I could make up my mind to accept it, being fully aware of the great difficulty in finding a subject worthy of detaining your attention. As a faithful reader of your admirable journal I cannot doubt that every topic of interest has been already dis-

⁽a) Paper read before the British Gynacological Society, June 8th, 1899.

cussed, that all scientific news reaches this important centre from all parts of the medical world, so that I do not for one instant flatter myself my communication will possess the interest of novelty, and merely propose to lay before you some results of my own experience on a field of investigation which has had its ablest explorers among yourselves.

Although it may be safely averred that the practice of specialising in medical science is daily gaining favour for the last twenty-five years, and that it is a step in the right direction, we must not wholly forget that it is

not always without its disadvantages.

Constant concentration of all our energies on the study of one particular organ, may, to a certain extent, be prejudicial to the demands of the general constitution.

We become one-sided in our views, and think, like Mephistopheles, we can "Alles curiren aus einem Punkt." On the other hand it will be conceded that the (general) practitioner will most likely fall into the other extreme—thereby neglecting to pay due attention to the morbid condition of a particular organ, in which often resides the cause of general-ill-health.

For it is not with man as with some lower animals, where the separate organs exist independently (to a certain extent) of each other. On the contrary, it is of vital importance to a generally healthy condition that each and every organ should be in good working order.

This being true for the physiological functions it is almost equally so, although not so easy of demonstration, with regard to pathological processes, and though it often occurs in cases under observation that certain affections remain for some time limited to one particular organ, it will nevertheless be found that ultimately the whole system suffers, through some reflex or more direct

There is no necessity to insist upon the fact that the conditions of the generative organs in woman which even in good health have so strong an influence on the whole constitution, should, when affected, awake sympathy in distant organs, especially when taking into account the

modes of innervation.

We are not quite certain by which ways the reflex action leads from the internal sexual organs to distant organs, although it is certain that the sympathetic nervous system is an important factor. It is universally recognised that the whole genital system is innervated, particularly by branches originating in the plexus spermaticus and the plexus hypogastricus. By the first mentioned, ovary and tube are chiefly supplied. The second form on both sides of the lig. latum an important network of nerves, the plexus utero-vaginalis, where also congregate smaller branches of the plexus spermaticus, continuing its course through the layers of the lig. latum to womb and vagina.

The sympathetic nervous system must, therefore, be considered as the track along which is flashed the irritation originating in uterus and appendages, in a different

direction.

It is now seven years since I first endeavoured to show, statistically, the very frequent occurrence of affections of the reproductive organs in woman. Since then there has been ample proof of my conclusions being correct. How can it, indeed, be otherwise, if we consider the enormous stress brought to bear on the internal sexual organs, not only by their complicated functions, but also by the many noxious influences to which they are exposed, and in the first place the fact that the peritoneal cavity is by way of the ost. abdomin. tube in continual contact with the outside.

From these facts we are naturally led to conclude that in all cases where the morbid symptoms do not point decisively to definite affections of remote organs, they must be investigated anew, from a gynecological point of view and similarly, when the hitherto adopted therapy, based on the conclusion that distant organs had been solely affected, has not led to satisfactory results, gynæ-

cological treatment should follow.

These considerations gradually gaining ground and recruiting more and more adherents in the medical profession as time goes on, it could only be expected that gynæcology should conquer, as it has done, an important rank among the independent sciences.

We have only to be careful that a trop de zèle, or misplaced optimism, should not lead to overstepping the limits of our field of action.

This is why I wish to bring before your notice that anomalies of the pelvic organs, although insignificant quoad functionem and quoad vitam, may nevertheless be the cause of serious disturbance to the general state of health. These disturbances which I have already qualified as distant symptoms, are generally to be recognised by nervous complaints, functional disorders of the nervous system, which very often, through summary diagnosis, cause the patient to be unjustly branded as hysterical.

To my great satisfaction I see my opinion on this particular side of the question viewed in the same light, and even expressed in almost the same words by Dr. Macnaughton-Jones, who writes in his interesting paper on uterine reflexes; "It is something more than injustice to her (a woman) if we deliberately and complacently ignore the influence that such local disease exerts in exciting morbid impulses in her central nervous system.

In order to elucidate this question, I propose to give a brief sketch of what has been written latterly on the relationship of genital affections with disorders of other organs adding the result of my own experience.

To take the bull by the horns, we will start by dis-

cussing the abnormalities of the nervous system. have long constituted the bone of contention between the specialist and the general practitioner, and a cause of dissension among specialists themselves, gynæcologists and neuropathologists alike. It has been long an established fact that the genital organs even in the exercise of their normal functions are frequently the agents of psychical disturbances. We know all about the pyschoses of pregnancy and of the puerperal condition, and are aware that the climacteric period can be, with predisposed persons, the time of life when neuroses or even more severe psychical troubles arise.

It is not even necessary to be one of the medical profession to note the powerful influence exercised by

sexual life on the nervous system of women.

The consequences are often too serious to be set aside. They govern both intimate and social intercourse. subject has engrossed the attention of novelists, at least on the other side of the Channel; has taken possession of the stage with, to my thinking, disastrous results

with regard to healthy physical and moral life.

It follows naturally that sexual suffering should demand a still greater degree of attention in the pathogenesis of psychoses. The only difference of opinion exists as to the frequency of its occurrence.

Neurologists and gynæcologists take opposed views, and on both sides there is much exaggeration to be

regretted.
Whilst the neuropathologist will scrupulously avoid all local treatment, for fear it should aggravate the psychical troubles, many gynæcologists exaggerate the importance in one or other form of sexual troubles regarded in the light of an etiological symptom.

Hegar, in his excellent paper on this subject, gives the

following resume of his observations :-

"Der Eine hat guten Erfolg mit seiner das Allgemein-befinden, und das nerven System allein berücksichtigenden Behandlung und der Andre heilt die anscheinend sehr schweren Leiden durch einen Ring oder einen vielleicht ungefährlichen operativen Eingriff.

"Jeder beurtheilt nur die andre Disciplin oder deren Vertreter nach solcher Vorkomnissen, und bedenkt nicht dass er nur die von dem Andren nicht gebesserten Kranken zu Gesicht gekommt, während er die Geheilten nicht sieht.'

Investigations made by several writers on the frequency of genital affections among the insane, vary considerably as to the result.

Eisenhardt gives the following:—("Die Wechsel bezie-In 100 cases of psychosis with genital abnormalities, Claus found 15; Kerkley, 27; Gnauch and Rippug, 33; Hertz, 66; Rohe, 74; Danillo, 80, mostly cases of chronic inflammation and displacement of the womb. nervous disorders were principally epilepsy, hystero-epilepsy, hypochondria, hysteria and neurasthenia.

Digitized by Google

I was fortunate in finding a wide field at Amsterdam Lunatic Asylum, which was kindly placed at my disposal

by the director.

The result was, however, not wholly satisfactory, owing to the difficulties of examination. Many of the patients could not be submitted to it without the aid of anesthetics, and of course it would not do, for the sake of gratifying scientific curiosity, to place under chloroform either the recalcitrants or virgins with narrow introitus.

The Asylum numbers 60 female patients, 41 of whom seemed to be suitable subjects for this examination.

Of these, thirteen were intact virgins, who could not easily be submitted to bimanual examination, which nade it difficult to discover possible disorders of the adnexa, and rendered the use of the speculum impossible. One had acute vulvo-vaginitis, and with the others I found a small anteflexed uterus.

There were also eight cases of senile atrophy, remarkable for their existence at a comparatively early age.

(One of the patients was 36.)

In the twenty-one remaining cases were found four displacements and nine chronic inflammatory diseases of the uterus or appendages; with the eight others no

genital disorder was discernible.

In calling attention to these facts it is not my purpose to draw conclusions. In order to do so they would have to be substantiated by longer observation. I only wish to point out that in many instances there was marked corelation between the genital and mental disorders, although in others it could be attributed to casual complication.

As a general rule, it can be stated that psychic or nervous troubles arising from disorders of the sexual organs have only been observed in predisposed persons, i.e., those with neuropathic tendencies, or else hereditary taint, and are rarely if ever found with a thoroughly healthy condition. The local symptoms that precede neurosis are, in the first place continual hæmorrhage and purulent discharge, also nerve irritation and neuralgia caused by pressure or stretching; therefore the symptoms observed in tumours or exudates, but more than all in uterine displacements.

An inquiry into the nature of the influence exercised by gyræcological treatment in cases of psychoneurosis is of great importance. It is generally considered that constant manipulation of the genitalia, particularly massage, ought to be avoided in cases of nervous or

hysterically-inclined persons.

To my thinking the psychic influence of this treatment has been judged erroneously. Personally, I am not an advocate for gynecological massage, the result being too uncertain, and the mode of treatment painful for the patient and fatiguing for the physician, whilst it also takes up a great deal of time, although I do not unconditionally subscribe the assertion that it produces hysteria.

But neither do I admit that, as some gynæcologists advise in these cases, total extirpation of the womb should be resorted to as a last resource. Why? I ask; if treatment of the diseased organs only serves to aggravate the original disease instead of affording relief, how can it be thought that total ablation can cure it. Can any one seriously entertain the idea that removal of the

uterus can cure hysteria?

Statistical researches have been instituted in England and America concerning the occurrence of psycho-gynæcological operations, with the following results:—Savage found, after 500 abdominal sections, four cases of mental derangement. Kinkley only one in 596. Investigation by Roke (New York Medical Journal, October 14th, 1893) shows the more important fact that in all the lunatic asylums of the United States and the English colonies, in the course of ten years, only 25 patients were registered who had become insane, after a gynæcological operation. To Czempus-Ebell's observation that perince-plastic operations are liable to bring about psychoses, I can but add the result of my own experience,

which shows in 85 perinæorraphies, only one case with this complication. This occurred where curettage had been previously practised, necessitating the use of anæsthetics twice in four weeks time. As for the rest, in rather a large number of benign and also more serious operations, I have never observed the appearance of psychical troubles.

On the other hand, recovery from neurasthenia has often resulted from gynæcological interference. It would take up too much of your valuable time to make any reference to the numerous bibliographical communications on the subject, and it will be sufficient for my present purpose to remind you of the wordy war that still continues to be waged on the subject of the indications and prognosis of castration for psycho-neuroses.

Battey, and (about at the same time) Hegar were the first who published the results of their experience. Since then casuists are continually increasing in number.

One hundred and forty-seven cases have been tabulated by different authors, showing eighty-two cures, twenty improved conditions, twenty-five with no improvement, six worse since the operation, and fourteen where the result had not been known. Personally I have but once practised castration for a case of hystero-epilepsy, but although the operation was successful and the patient made a good recovery, the final result was not satisfactory, as she had a fit once afterwards, shortly before the menses which continued pretty regular, notwithstanding the removal of the adness.

In the greater number of my cases I have seen mental troubles disappear after gynecological treatment, but will only refer to the following, as being the most typical.

Miss v. H., at. 37, suffered many years from chronic ophoritis and peri-ophoritis dextra, causing violent pains, emaciation, and all the typical symptoms of neurathenia. Careful local treatment had been of no avail; the patient, a highly intellectual person, became worse and worse, her condition degenerating into complete melancholia, until she only longed for an end to her unhappy and useless life.

On ber own express desire, as a last chance of regaining her energy, castration was practised February 17th, 1890. Eleven months later she wrote to tell me she felt thoroughly well in health and spirits, and, as nurse at a hospital, was able to undertake all her duties, even those

making a demand on muscular strength.

With regard to its etiology Basedow's disease should be mentioned among the foremost of nervous maladies

that stand in relation to genital disorders.

It attacks women four times oftener than men, generally between the ages of 16 and 30, and frequently occurs as a complication with pregnancy. Menstrual disturbances constitute one of the principal symptoms, and it has often been observed in cases of amenorrhœa that the characteristic symptoms of the primary illness, exophthalmos, struma and tachycardia increase with the return of the menses. Some writers, for instance, Eulenberg and Mathieu have observed the occurrence of morbus Basedowii after a gynæcological operation, but on the other hand a greater number of recoveries are due to gynæcological interference, in cases where it has been coexistent with genital disorders.

To these I can add a case of my own, where in view of the result obtained, there could have been no doubt

whatever as to the causal relationship.

Mrs. De H., from Medan, was sent to me with symptoms of chronic endometritis, and subinvolutio uteri, post abortum; added to these, the symptoms of morbus Basedowii were beginning to make their appearance, so that her return to Europe could be no longer delayed. After curettage in October, 1893, all bad symptoms had disappeared in the space of a few months. Since her return to India I received information that she had been confined of a living full-grown child.

In another case of fibro-myoma uteri I found also con-

siderable thyroid enlargement.

The patient came under my charge, and I removed per laparotomy, March, 1892, a large myoma, quite filling up the small pelvis. Two days later the struma was much smaller, and, since, there has been no recurrence. Affections of the peripheric nerves are also found associated with sexual disorders. Ischias, intercostal-

neuralgia, hemicrania, &c., are not only founded on hysteria, they also appear sometimes as characteristic reflex-phenomena.

Odebrecht communicates a case of trigeminalneuralgia which disappeared subsequently to ventrofixation, after pessaries had been previously applied in vain.

Foremost among the organs that either by direct or reflex action, are liable to be affected by sexual disorders,

The pathological changes in this organ which are sometimes due to disturbances of the circulation and sometimes purely functional, consist, in the worst cases, of iridochoroiditis, and can sometimes lead to atrophy of the opticus. Chronic anemia, induced by menor-rhagia or metrorrhagia, therefore principally the result of neoplasms and pseudo-endometritis, may also be the cause of dire misfortune to the organs of sight, either in the form of accommodational disturbances or inflammatory processes, amblyopia or amaurosis, whilst optic-apoplexia even solution of the retina, iritis and keratitis have been found in association with abrupt suppressio menses. I have in my practice numerous cases of choroiditis, iritis, episcleritis, where on evidence of the therapy that had been employed, the origin could be traced to chronic

With regard to circulation, acceleration of the heart action is the most prominent feature, I have frequently observed troublesome palpitations give way, on recovery from chronic endometritis. Structural changes of the heart can also be accounted for by the existence of

genital disorders.

A well-known sign of myoma uteri is the brown atrophy of the cardiac muscle which has been accounted for by the decrease of hæmoglobin in the blood, and whereby the muscle is condemned to harder work with less nourishment. Next come disturbances of the digestive organs, in the list of evils to be brought home to sexual disorders. Hildebrandt is right where he asserts: "Bei magenleidende Frauen sollte man füglich wegen der imgemeinen Haufigkeit in welcher Magenleiden folgen von Erkrankungen des Uterus sind, niemals eine Untersuchung der Genitaliën unterlassen, auch wenn sonst keine symptome auf eine Erkrankung der Geschlechtsorgane hinweisen.

Gastric disturbances are mostly brought about by reflex action and are chiefly observed with nervous persons. According to Graily Hewitt 14 per cent. of the sufferers from uterine disorders complain of troubles of the digestive organs, the minor symptoms being a feeling of heaviness on the stomach, pains, nauses, &c. In many of these cases the symptoms become aggravated to such an extent, that even if life itself is not threatened, it becomes a burden to the sufferer.

The lightest food cannot be retained, emaciation and cachexia set in, bringing on mental depression that

sometimes ends in true melancholia.

In none of these cases were any perceptible change in the secretions of the stomach observed.

Neither the secretion of hydrochloric acid nor that of pepsine has been in any degree modified. The trouble originated in affections of the endometrium, or with displacements, particularly with retroflexion, and numerous are the recoveries due to timely and efficient treatment of the primary disorder. I will now only mention one case which seems to me particularly characteristic.

Miss v. d. F., æt. 39, came to my clinique to be treated

for uterine hæmorrhage. She had always menstruated over-abundantly; since two years profusely and in advance, and for the last year she was continually losing blood, the menstrual type being still recognisable by blood, the henstrain type being sun recognizated by exaggerated bleedings every three weeks. In August violent flooding, which greatly reduced her strength Between times she had a profuse greenish watery discharge. Great suffering was caused by a very bad state of the digestive organs, which she dated from her eighteenth year, when after a fall from a ladder, she had been carried home senseless. Ever since she had been unable to retain anything but liquid nourishment, and had occasionally vomited blood. On examination the uterus was found movable and unenlarged. Curettage on August 15th, removed a quantity of friable mucous membrane. The uterine cavity was then stuffed with

iodoform gauze, and treatment continued by cauterisation with chloride of zinc. The scraped-out membrane was microscopically examined, and found to contain besides portions of healthy tissue typical cancerous gland-tissue.

The entire movability of the uterus seemed to give the ideal indication for total extirpation, although the severe digestive troubles gave matter for serious deliberation. As long as she had been in the clinique the patient was unable to retain any food, not even milk or eggs, which were usually vomited during the night or towards morning in the form of a foul-smelling, frothy mess. The tongue was white and furred, and the appearance of the patient enfeebled and cachectic. A complication with carc noma ventriculi was naturally thought of, but there were no symptoms of a tumour in the regions of the stomach, neither were there traces of blood in the vomit. The difficulty lay in solving the problem of etiological co-relation between eventual cancer of the stomach with the evidently young carcinoma of the uterine mucosa.

After mature consideration I concluded for the total extirpation per vaginam, which I performed January, 1894.

The patient made an excellent recovery, and was quite well when she left the clinique at the beginning of February. Remarkably enough, there had been no more vomiting since the operation; not only milk and eggs were retained, but a careful experiment with more substantial food was successfully sustained.

Desirous to know the ultimate result, I wrote to the family doctor, who replied in June, '96, to the following effect :- "Miss F. has been in good health ever since her return home, and has not required any medical assistance. I have had the opportunity of seeing her twice or three times every week for the last two years, as her mother is a patient of mine. She is looking remarkably well, all digestive troubles have ceased except occasional constipation, which is easily conquered by a mild purgative. There is every reason to trust to the nonrecurrence of carcinoma, as since the operation, not one bad symptom had arpeared.

It is sufficiently obvious that frequent disturbances of the urinary excretions and secretions should occur when taking into consideration the anatomical relationship of the bladder and urethra, with the internal generative

organs.

Leaving aside the numerous direct troubles such as urine retention in cases of tumours or retroflexio uteri gravidi, prolapsus vaginæ, with cystocele, cystitis resulting from blenorrhagic infection, and pruritus vulvæ from diabetes, we have pathological deviations in the uropoietic organs of which some can be considered as reflex-symptoms.

Tenesmi ad vesicam, as well as polyuria and anuria, are frequently observed to be symptoms of endometritis, which disappear with the disease, in the same way as retentio urinæ occurs after various gynæcological

operations.

Pathological deviations of the genitalia, besides their disturbing influence on the functions of the bladder, produce anomalies of the kidney which can be easily traced to the same origin.

Virchow first pointed out the origin of hydronephrosis in prolapsus vaginæ and hypertrophy of the portio vaginalis and supra-vaginalis uteri. Freund and Hildebrandt communicated cases of hydronephrosis resulting from the bending of the ureters in cases of retroflexio

The wandering kidney is often found associated with disease of the female sexual organs, especially displacements of the womb. Landau has observed the wandering kidney 273 times in women to 41 in men—and according to Sulzer's statement, 85 per cent. of sufferers are women.

The dislocation of the kidney has been ascribed to various reasons, among others, individual disposition and inappropriate clothing, also to a decrease of the intra-abdominal pressure or rapid decrease of the fatty tissues.

The first symptom appears in persons with flabby abdominal walls, generally accompanied by relaxation of

the peritoneum and its duplicates, which support the abdominal organs.

When we consider that this slackening mostly occurs after pregnancy or the removal of abdominal tumours, we have not long to seek why women are such frequent sufferers from the rein-mobile.

Thiriar also indicates causal relationship between reinmobile and disorders of the sexual organs, and observed that after nephropexy there came a simultaneous end to menstrual anomalies and chronic inflammation of the mucous membrane, and he explains this connection by pressure from the dislocated kidneys on the venæ of the plexus spermaticus.

Before concluding, I would call to mind the frequent occurrence of some skin diseases under the influence of pathological deviations of the generative organs.

It is known by every one that many women have during the menses a bad complexion and not infre-

frequently eruptions.

Pigmentary formation, chloasma uterinum, and discoloration of the linea alba, are universally recognised among the symptoms of pregnancy. Hebra, in 1855, first called attention to the causal relation between a certain class of skin diseases and disorders of the genitalia.

Among others, he mentions a case of eczema and urticaria which was completely cured without local treatment by the removal of an inefficient pessary.

Later on, Schauta investigates, and is able to make a statement proving undeniable correlation in 26 cases, where the genital disorders were mostly retroversio, chronic endometritis, salpingitis, and principally myoma uteri.

In the selection of my subject I have been chiefly actuated by the desire to make use of this opportunity to speak to you of my views on a matter I have always had very much at heart, and to express my entire con-cordance of opinion with Dr. Macnaughton-Jones, by whom you have been addressed in a far abler manner, and others, who think with me, that all the varied forms of misery, liable to be brought about under the influence of a pathological condition of the sexual organs, on the whole constitution of a woman, cannot be overrated; or, to quote once more Dr. Macnaughton-Jones, "All we know of the physiology of uterine action, compels us to regard the uterus and ovaries as the strongest links in the chain of the woman's health of mind and body."

Nothing can be further from my meaning than to insinuate that every ailing woman should be submitted to a gynæcological examination. Far from that; however undeniable it is that any organ may be influenced by sexual diseases, objective examination would reveal a marked difference between these symptoms and the symptoms belonging to primary disorders of these organs. It would never enter my head to suggest the necessity of gynecological examinations to a woman who came to me with the characteristic symptoms of gastric catarrh, or a well-defined heart disease, and even should there be evidence of a co-existent abnormality of the generative organs it might turn out to be after all a chance complication.

On the other hand, when objective examination of the distant organs and haphazard therapy have merely led to negative results never should the importance of a gynecological examination, ad ultimum refugium, be allowed to pass, even in cases where there have been no

subjective symptoms of genital disorders.
Positive results will often be obtained by taking Positive results will otten be obtained by waring this measure, after which there still remains to be solved the question of etiological relationship; and if, therefore, the abnormality that has been revealed, is of a nature to legitimate local treatment, according to the consumerabould he a decided "yes." to my conviction the answer should be a decided "yes. Now that it is universally recognised what important factors the sexual organs either in a diseased or healthy condition are in the organism of women, bearing in mind this unmistakable truth, no physician has the right to deny his patient, perhaps the only chance of delivery from a burden of physical and even mental misery, sufficient to poison her life. When choice lies between an operation or any other mode of treatment, it should be remembered that where there is excessive

nerve-irritation, hysteria or neurasthenia, the first is preferable, when it has been proved that a short course of local treatment has not borne satisfactory results.

I have, for instance, observed the so called uterine dyspepsia resist for months, continued cauterisation of the endometrium, when curettage being tried, the

desired effect was easily obtained.

Needless to add that I am always careful in drawing conclusions from first favourable results; unfortunately enough my patients have sometimes returned after an interval of good health with the same complaints, for which they had first sought relief, although the local disorder had completely disappeared.

The cases, on which my conclusions have been based, concern patients that have been at least two years under observation, consequently all doubts concerning the question of causal relationship are completely removed.

I have now only to thank you for your kind attention and hope you will have overlooked, possible faults in expression, due to my unfamiliarity with your language.

Transactions of Societies.

BRITISH GYNÆCOLOGICAL SOCIETY. MEETING HELD THURSDAY, JUNE 8TH, 1899.

The President, Dr. MACNAUGHTON-JONES, in the chair.

DECIDUOMA MALIGNUM

DR T. W. N. HAULTAIN (Edinburgh) showed a specimen of this growth, together with microscopic sections, and gave a lantern demonstration of micro-photographs. (We hope to publish Dr. Haultain's paper with a valuable series of illustrations in our next, on completion of the necessary engravings.)

Dr. Mendes de Leon (Amsterdam), read a paper on GENERAL DISORDERS ORIGINATING IN DISEASE OF THE FEMALE PELVIC ORGANS,

which will be found in another column among "Original Communications.

In the discussion which followed, Dr. HEYWOOD Smith said that Dr. Mendes de Leon's conclusions must find an echo in the experience of most of them. was no doubt that the weman was built up around her pelvic organs, so that it was not surprising that there should be so many reflex disorders associated with diseases of those organs.

Mr. CHARLES RYALL thought that they must all feel much indebted to Dr. Mendes de Leon for his interesting paper. They were all familiar with the uterine reflexes, but they were apt to forget that diseases of other organs might simulate disease of the uterus and ovaries. Movable kidney afforded an example. Thus he had recently a case in which the patient complained of much pain in the pelvis and of intermenstrual pain. One surgeon advised oophorectomy, and this was done, but she was not relieved. Then another surgeon advised hysterectomy, and this was done, but still she was no better. It was then found that she had a mobile kidney, and after nephropexy had been done she got all right. Mastodynia was often found associated with uterine disease, but it might be due to interstitial mastitis.

Dr. Burleigh-Robinson thought that the question of the relation between gynæcological operations and mental conditions was an important one, and he hoped that some Fellow would bring forward a paper on the subject of operations on the insane.

The PRESIDENT said that at a former meeting of the Society they had had a discussion on the relation between pelvic disease and mental conditions, several well-known alienists taking part. The subject had been studied more especially in America, and it had been shown that there was frequently a definite relation between the two factors. British psychologists were agreed that if there was uterine disease in a woman who was insane, the patient should be examined, and treatment adopted by operation or otherwise whenever this was possible. He had seen three cases in which women in a condition of 668 THE MEDICAL PRESS.

Dr. Mendes de Leon, in reply, said that of course he knew that he could not exhaust such a subject as he had chosen for his paper. He thanked the Fellows of the Society for the attentive hearing they had given him. The one point on which he wished to lay special stress was the importance of not vaguely relegating to the category of hysteria, patients who might be suffering from organic pelvic diseases.

BRITISH ORTHOPÆDIC SOCIETY. MEETING HELD IN THE ROYAL INFIRMARY, DERBY, SATURDAY, MAY 27TH, 1899.

Mr. Gentles in the Chair.

Mr. William Thomas showed a patient in whom the left popliteal nerve had been injured by a kick from a horse, talipes equino-varus having occurred as the result. Neurorraphy having failed. he performed tarsectomy. The result appeared to be excellent.

Mr. Tubby pointed out how very difficult it is to get the ends of a divided nerve together when the division occurs close to where the trunk breaks up into

Mr. ROBERT JONES called attention to the slight amount of power still remaining in the extensors of the toes, showing that the nerve was not entirely divided or else that some union had occurred. He could not under-

stand how the tarsectomy could prevent the foot-droop.

Mr. Bennett contrasted a case under his care where the ulna nerve was injured by fracture of the lower end of the humerus without division; but at the operation the sheath alone was found to be intact, the nerve elements being completely divided and retracted inside it. In that case an inch and a half of a rabbit's sciatic nerve was inserted with success. He asked why the author did not try nerve-grafting.

Mr. MUIRHEAD LITTLE mentioned a case in which the peroneal nerve had been divided six years before it came under his care, in the course of an operation for division of the biceps tendons. Talipes equino-varus had resulted. He cut down and found a gap of about two inches. The upper end of the nerve was bulbous, and the lower a good deal wasted. He excised the ends and succeeded in getting the cut surfaces in apposition by flexing the knee. No benefit resulted, however, probably because the injury was of such long standing. He asked whether Mr. Thomas might not have got the ends together in his case by a similar manœuvre.

Mr. Luke Freer remarked that after tarsectomy in ordinary talipes equino-varus there is often a relapse. To avoid this it might be well to continue with stimulation of the nerve by battery and foot kinetics.

Mr. Thomas, in reply, said that in addition to tarsectomy he divided all the flexor tendons. He thought He thought that union of the bones caused rigidity of the foot, and he laid great stress on the importance of removing a large piece of skin in tarsectomy. The nerve was never completely divided. This fact would probably account for the slight power left in the extensors, and for this reason he refrained from nerve grafting. He tried flexion of the knee, but did not find it approximated the ends of the nerve to any extent. He did not think that the battery was of much use. The voluntary use of a muscle was of far more use in stimulating development. than electricity or massage.

Mr. CARWARDINE read a paper on a case of Talipes Equino-Varus, treated by Phelps's latest operation. chief points in the operation are-1. To thoroughly disinfect the skin. 2. Constant irrigation with an antiseptic during the operation. 3. To make an open incision on the inner side, if the skin be short. 4. To cut all the parts in order of their resistance, first dividing the tendo-Achillis, if tense, then tibialis posticus, abductor pollicis, plantar fascia, flexor brevis, long flexors, deltoid ligament. 5. Then when necessary linear osteotomy of the neck of the astragalus. 6. Resection of a wedge of bone from the os calcis, the point meeting the osteotomy wound through the astragalus. The operation was performed on June 30th, 1888. The boy did well, and on November 14th the following note was made. Foot perfectly straight, walks fairly, good flexion, extension, inversion and eversion. inversion, and eversion. Good arch to foot, the normal length of the foot preserved, and no tenderness of the scar. He said that the special feature of the complete operation is the alteration of the bony axis of the foot without diminution of its length, the inner bord r of the foot being lengthened. The transverse tarsal joint and great synovial membrane of the foot are not interfered with, so that the foot preserves its natural mobility and elasticity.

Mr. LITTLE said that he had had some experience of Phelps's operation, and had got very good results, and had seen no tendency to relapse, or any troubles due to the scar. It was important that the wound surfaces should be kept apart as long as possible; hence healing must be very slow. He thought it better to lengthen the inner border of the foot by Phelps's operation rather than to shorten the outer border by tarsectomy.

Mr. KEETLEY raised the objection that the scaphoid was not replaced in its proper position over the head of the astragalus in the operation as represented by Mr. Carwardine, and he thought that the scar must tend to cause relapse. The large granulating surface in Phelps's operation was, he thought, a danger.

Mr. W. Thomas saw no advantage in this operation over an ordinary tarsectomy.

Mr. R. Jones preferred Lund's operation of astragalectomy, which in his hands had yielded most satisfactory results.

Mr. CARWARDINE, in reply, said that he thought that the rigidity caused by tarsectomy was objectionable.

Mr. CARWARDINE read a paper on Congenital Absence of the Fibula with Intrauterine Fracture of the Tibia. The patient was five weeks old. The right leg was much shorter than the left, and the thigh half an inch shorter. The leg was bent rather below the centre almost to a right angle, and over the convexity was an umbilicated and somewhat adherent scar. The fibula and all the elements of the fifth toe were absent. The tibia was sharply bent upon itself almost to a right angle, with some thickening of the part. The tendon-Achillis and skin posteriorly were very tight. (Skiagrams and sketches shown.) When the mother was two months pregnant she was nearly run over by a carriage and pair. To escape the danger she made a sudden dat forwards. He corrected the deformity with great diffi-culty, owing to the hardness of the bone and tenseness of the tendon Achillis, which he divided. He was of opinion that the condition was a true greenstick fracture of one tibis across the other in utero by contrac-tion of the parietes upon a bone which lacked the sup-port of the fibula. The absence of the fibula and fifth toe are developmental.

Mr. R. Jones thought that no theory of etiology fully accounted for the conditions found. It was difficult to conceive of any direct injury to the mother giving rise to a compound fracture of the tibia when surrounded by amniotic fluid. The large proportion of cases giving evidence of congenital irregularities of toes seems to

suggest a joint causal relationship.

Mr. Luke Freer referred to his case recorded in Vol. I. of the British Orthopædic Society's Transactions, in which the fibula seemed to shade away with the tendo Achillis.

Mr. CARWARDINE read a paper on Tuberculous Abscesses

and their radical cure by thoroughly scraping and irrigating the cavity. The three cases he had operated on with complete success were: 1. Large abscess of the thigh from tuberculous disease of the pubes. 2. Large tuberculous subgluteal abscess of the thigh, probably of spinal origin. 3. Psoas abscess extending over the whole front of the thigh, the result of tuberculosis of the vertebre.

Mr. Luke Freer exhibited two skiagrams: (1) Congenical displacement of the left femur. (2) Right coxa vara associated with lateral curved femora of rachitic origin.

Mr. Tubby read notes of a case of "Spastic Hemiplegia, with flexion of elbow and wrist and pronation, treated by open section of the flexor tendons, especially flexor carpi radialis, and detachment of the pronator radii teres from its insertion." A hole was then made in the interosseous membrane, and the tendon passed round the back of the radius to its outer border, and fixed; thus reversing the action of the muscle. Patients after six weeks could pick up a pin. He kept the wrist during this time midway between flexion and extension by splints.

Mr. Keetley opened a discussion on "Coxa Vara." He described types of the two great varieties, which commence in adolescence. The deformity was rachitic in origin. The partial, or even total, absence of rachitic change in other parts was no disproof of this, as the older the patient the more localised the rachitic changes tend to be. The various modes of osteotomy which had been carried out or proposed, including a new method, were described. In theory the neck of the bone should be operated on, in practice the trochanteric region was more convenient. Decreased angle of the neck and shaft formed the striking feature on a first glance at the deformity, but the main changes were in the neck itself, especially near the head. In fact, coxa vara was rachitic deformity of the upper epiphyseal region of the femur. The deforming influences sometimes extended far down the shaft. Compensatory genu valgum was common. The speaker called attention to a peculiar expansion of the facial bones, giving prominence to the eyeballs and width and flatness to the upper half of the face. Coxa vara in cases of early rickets was very common indeed, but during adolescence were rare. The commencement of the flood of modern literature on the subject dated from the speaker's own paper, in the Illustrated Medical News, for September 29th, 1888. The hip-joint was healthy in these cases. For this and for other obvious reasons, excision was not justifiable.

Mr. R. Jones said that he thought that a transtrochanteric osteotomy would do all that was needed in these cases.

Mr. Tubby said it would be adviseable to divide the adductors, and after doing transtrochanteric osteotomy to transfer the attachment of the abductors from the great trochanter to the lower fragment, so as to increase their power of action and abduct the shaft instead of the neck of the femur.

Mr. Muirhead Little pointed out that the deformity in infantile coxa varæ was very different from the adolescent variety. It seemed to be a process sui generis. Charpentie had shown that ostitis might cause the deformity.

Mr. Keetlev, in reply, said that he did not think a simple linear osteotomy was enough, though when ankylosis existed, as in coxitis, a linear osteotomy sufficed because the upper fragment was fixed. Coxa vara was very common in infantile rickets, and often accompanied genu valgum. He believed that some cases described as separation of the epiphysis were really cases of coxa vara

THE receipts from the great bazaar at the Albert Hall, held last week in aid of the funds of the Charing Cross Hospital, amounted to £13,300 for the two days. This exceeds by £3,300 the amount which was realised by the Press Bazaar at the Hotel Cecil.

THE BRITISH BALNEOLOGICAL AND CLIMATO-LOGICAL SOCIETY.

MEETING HELD THURSDAY, JUNE 1st, 1899.

The President, Dr. R. FORTESCUE Fox (Strathpeffer Spa), in the Chair.

Dr. H. Shirley Jones read a paper on

THE TREATMENT OF NEURITIS AND NEURALGIA BY THE DROITWICH BRINE BATHS.

Dr. Shirley Jones said he considered obstinate neuralgia and neuritis for the most part associated with, and dependent upon a debilitated condition, and believed gouty neuralgia to be more the result of weakness, than the effect of any uric acid on the nerve itself. The nerve most affected is the sciatic, for obvious reasons, for it is the most difficult nerve to rest, and the large surface over which it extends renders it more prone to injury from cold, &c. Next in frequency is perhaps the fifth. Obstinate cases of neuralgia are met with accompanying malignant diseases. He had seen also three cases of sciatica following the apparently successful removal of mammary carcinoma, which would only admit of very temporary relief. Each case died within two years of onset without any material benefit, or any evidence of return of malignant disease. He related three cases of intense neuritis leading to insanity.

Dr. Douglas Kerr (Bath) said he could testify to the benefit which he had known in severe cases of neuralgia from the Droitwich bath treatment. He asked Dr. Shirley Jones for particulars of treatment.

The President remarked that neuralgia in its various forms was usually relieved under balneological treatment. It acted, doubtless, as an eliminant. and also tended to remove the subinflammatory conditions on which most cases of neuralgia depended. He also called attention to the use of cold douches for neuralgia by the French.

Dr. Bowen Davies (Llandrindod Wells) asked for further particulars of the methods of treatment at Droitwich.

In reply, Dr. Shirley Jones said he had chosen this subject as being of interest, because he thought more brilliant results were obtained from these waters in cases of neuralgia and neuritis than in any other disease. These cases of neuritis which he had mentioned, showed a peculiar obstinacy, and each led to a very unusual complication, viz., insanity. The treatment he adopted at Droitwich in neuralgia and neuritis consists for the most part, for acute cases in the use of a hot reclining bath without massage or electricity, but with as complete rest as possible. In cases of the lower limb rest in the recumbent position. for the upper limb rest in a sling, and in uncomplicated cases no drugs at all. For the relief of pain he used hot brine as a compress. As the acute stages pass off the douche over the course of the nerve comes into use, the temperature and the length of time varying considerably with the amount of pain and idiosyncrasies of the patient from, 115 degs. to 80 degs. usually, and he had occasionally found great benefit from a temperature as low as 65 degs. given as a douche, particularly in cases where there had been atrophy of muscles resulting from a neuritin; there too he found great benefit from the use of the swimming-bath where owing to the great buoyancy of the water, exercise of any limb may be effected with a minimum of exertion, and this he thought a very important point in the development of atrophied muscles; apart from that the swimming bath has a very decided tonic effect, and as such is very useful in the treatment of chronic neuralgia.

Dr. Ivor Murray read a paper on "Scarborough as a Health Resort in Phthisis" which led to some discussion.

A DESPATCH from Alexandria states that two fresh cases of plague have occurred there, the patients being natives.—Reuter.

France.

FROM OUR OWN CORRESPONDENT.]

Paris, June 25th, 1899.

CREOSOTE AND PHTHISIS.

At the Academy of Medicine, M. Bucquoy read a paper on the "Treatment of Consumption by Large Doses of Creosote." He said that of all the therapeutic agents tried in this disease, creosote was certainly the best, and opinions differed only as to the dose that might be given. He had known cases in which from one to two drachms were given with impunity in the twenty-four hours; on the contrary, an increase of appetite and a decrease of the sweatings, and, above all, of the expectoration were obtained; the fever also yielded notably. In no case did the drug cause irritation of the stomach.

CACODYLIC ACID.

M. Daulos said he had employed for the last two years cacodylic acid internally and externally. Externally he used a solution of 50 to 75 per cent. of the non-neutralised acid, but internally he preferred the neutralised acid, that was to say, cacodylate of soda. He gave it by the mouth, or by subcutaneous injection. Taken by the mouth it left a disagreeable taste in the throat, and to obviate this he was in the habit of using the following formula—

Ram β 5iv;
 Water, 3ij;
 Ess. of peppermint πj.

A teaspoonful of this mixture represented exactly two grains of cacodylic acid.

It could also be prescribed in pills with extract of gentian. The amount in each pill might be two grains.

He had thus treated psoriasis, acne, lichen, lupus, cutaneous tuberculosis, tuberculous adenitis, &c., at the dose of from 8 to 12 grains daily for men, and half that amount in the case of women, and had obtained some satisfactory results. He would add, however, that he had seen two or three patients suffer considerably from colic.

HEMORRHOIDS.

M. Schwartz, at the meeting of the Société de Chirurgie, introduced the subject of the treatment of hemorrhoids, and said that those of small volume should be treated by dilatation and ignipuncture. He treated thus a considerable number of patients, and always successfully. In voluminous tumours he employed up to the last years exclusively the methods of volatilization of Richieb. For the last two years he practised the operation of Whitehead in a certain number of cases, but he should add that the operation was very tedious, and in some cases the patient lost a considerable quantity of blood.

M. Delorme said that he preferred Whitehead's method in all cases where the lesions were diffused and extensive.

M. Delbet considered that the thermo-cautery did not constitute a perfect hemostatic. On the other hand, its antiseptic action was beyond doubt, but to-day it was possible to obtain the same result by other means, with the advantage of procuring union by first intention, whilst that desirable result could not be produced by the cautery. Further, as a modifying agent, the thermo-cautery provoked an in-

flammatory process which was not without danger. When he was house surgeon under M. Richet, he had seen patients endure untold suffering after being treated by the volatilization of the hemorrhoids, and several succumbed to septic accidents. Unless the hemorrhoids were procident and ulcerated, he discarded the thermocautery in favour of the bistoury followed by suture. M. Tillaux regarded the thermocautery as perfectly hemostatic, on the condition that it was employed at a dull red, and that it was pressed on the tissues so as to break down the walls of the vessels. For more than thirty years he had treated hemorrhoids by ignipuncture, and always considered it as the simplest and the best method for that affection.

Germany.

[FROM OUR OWN CORRESPONDENT.]

BERLIN, June 24th, 1899.

At the Congress for Innere Medizin Dr Jacob, Cadowaa, read a note on

NEUROTIC INSUFFICIENCY OF THE CARDIAC MUSCLE.

He formulated the following proposition:-There is a form of disease similar to degeneration of the cardiac muscle, and also mistaken for it, that, in spite of dilatation and arhythmia, as well as equal size of the pulse, by a certain order in the disorder can be distinguished from a pulse of good tension, and notwithstanding the symptoms of insufficiency, allows of a good prognosis. It might be named pseudo-degeneration of the heart-There was a chronic tachycardia, with regular pulse and insufficiency easily mistaken for Basedow's disease, especially when associated with a slightly enlarged thyroid and prominent eyes. It differed, however, from Basedow's disease in the absence of the hot skin-on the contrary, the skin was rather cool-absence of thirst voracity, cardiac murmurs, in short, of all the symptoms of exaggerated tissue change. The patients did not bear cold bath treatment, but were improved by everything that relieved the anæmia. The condition improved in a short time, in as many weeks as the Basedow required months. The Basedow had not, with but few exceptions, a tense pulse. The insufficiency was such as arises from hyperenergy. Improvement took place most quickly, through measures that reduced the tension. The capacity of life of the heart was a constant product of its work with the time which this took to perform. Dilatation and tachycardia sprang from a common source.

Hr. Behuschky read a note on

THE DIAGNOSIS AND TREATMENT OF PRIMARY TUBERCULOUS ULCER OF THE STOMACH.

The speaker had observed two obstinate cases of ulcer of the stomach, the tuberculous nature of which was at last determined by the quick improvement that followed the use of tuberculinum Kochii. Continuance with the tuberculine treatment brought about a rapid disappearance of the symptoms of the disease in contrast with years of failure under other methods. The first case came under observation in 1892, the second only recently. The latter he considered to be a primary tuberculous affection. The patient was 35 years of age. He came of a non-tuberculous family; he had suffered from symptoms pointing to ulcer of the stomach for a year

and a half. Tuberculine treatment was at last begun. with a dose of 0.1 mgm., the second dose was 0.5, the third 0.1 mgm. The temperature rose to nearly 39 degs. C. With the reaction the pain disappeared.

Hr. Loewit, Insbruck, opened a discussion on LEUCÆMIA AND LEUCOCYTOSIS.

The most important distinction between the two lay in their different ætiology. Leucocytosis was not a disease of itself, but only a symptom. Its ætiology was therefore various, and was not yet worked out. The ætiology of leucæmia had hitherto been a dark region. From his own investigation he had taken up the position that it was an infection with hæmamæba of the class of sporozoa. He would not go further into the method of investigation adopted. They were objects coloured with great difficulty, and could only be seen under certain conditions, although they might be present in the blood and the blood-forming organs in immense numbers. His examination extended to twelve cases of myelæmia. The peripheral blood was principally examined in dried preparations. In one case it could be examined fresh. Parasitic elements were always found in the blood in varying quantities. They could be divided into several groups. First, a young form, small crescentic bodies, in the interior of which a nucleus-like body could be recognised; second, large well-grown amæba forms likewise, with one or several nucleus-like bodies; third, sporulation or segmentation forms (rarely caudated or whipped). The fourth group was the most characteristic, of an exquisite sickle shape; they were not frequent.

In order to examine the blood-forming organs, puncture of the spleen was performed three times on the living, and each time enormous numbers of these parasites were found in the juice of the spleen, far more than in the blood examined on the same day. His lymphæmia cases were limited to six, and they could only be examined in dry preparations. The body organs were only examined in four cases, two of them fresh. Examination of the peripheral blood was at first negative, with a perfected method of examination, peculiar bodies were found in the lymphocytes of the peripheral blood, which the speaker looked upon as parasitic elements, most probably identical with those seen by Mannaberg in 1896. With better standard methods he found form-elements in large numbers, which were much smaller than those of myelæmia. He had therefore selected the name hæmamœba leucæmiæ parva vivax.

He was able to examine a leucæmic swine spleen. There he found the same permanent forms as in human myelæmia. He had made transplantation experiments on various animals, with success in the case of rabbits. Changes were observed within twenty-four hours, which reached their maximum in ten or fifteen days. The number of leucocytes had increased to 50-80,000 and more per cubic millimetre. The animals lost in weight, this loss he could not properly explain. Typical albumosuria was found in the infected animals, no fever, at most a rise of temperature on the first and second day, not again. The animals lived from three to four days to ten months. Four out of twenty-eight rabbits injected showed a mixed infection of leucæmia and tuberculosis. Observation of the parasite in infused fresh blood of the infected rabbits was very easy, and heir movements could be followed.

He believed that the parasite formed the irritation that led to increase of leucocytes in the blocd and the blood forming organs, and on the other hand they were respon. sible for the great destruction of leucocytes. Investigation into the relation between the leucocytes and the parasite had made it probable that the morbid changes for the former were attributable to the life-activity of the latter.

As regarded therupeutics the analogy between leucæmia parasite and malaria parasite pointed to trial of quinine. He had tried it on two animals, one subcutaneously and one intravenously. The second animal died on the third day of acute quinine poisoning. The parasites disappeared out of the blood only just before death. On the other hand there was nothing in the body organs of this animal that indicated any association with hæmamæba. That was a very meagre result, but it lead to the thought that in our therapeutical strivings we must attempt to drive the specific parasite out of the body.

Austria.

FROM OUR OWN CORRESPONDENT.]

VIENNA. June 23rd. 1899.

SYMBLEPHARON FOLLOWING PEMPHIGUS CONJUNCTIVE.

AT the "Gesellschaft der Aerzte," Moruz Sachs exhibited a man with total symblepharon which had been produced by a former attack of pemphigus of the conjunctiva, and finally soldered the eyelids together, so that no line of separation remained to distinguish the upper lid from the lower, on the right, while the left had a centimetre opening revealing a thin membrane over the cornea that further impaired vision by this narrow opening. With the right eye he could distinguish darkness from light, with the left he could discern the finger at a short distance. A similar condition had partially affected the mouth, soldering the cheeks to the gums.

He concluded by describing the operation necessary for the restoration of sight, as plastic interference was the only remedy in such cases.

Schopf showed a patient who was under his care twelve months ago with an alimentary condition that was diagnosed as carcinoma ventriculi requiring resection of the pylorus. On opening the abdomen the stomach was found to be hard, and thickened along the greater part of its length, involving mesentery and omenti, the latter being studded over with small nodules. The whole of the stomach, except two inches at the cardiac end, was removed, after which the patient soon recovered.

The fresh specimen measured 20 cms. (7.87 in.) along the minor curvature, and 28 cms. along the major curvature. The microscopic examination revealed a lympho-sarcoma with diffuse infiltration, which reduced the lumen of the pylorus to a mere aperture that would not admit of the passage of a "match." Notwithstandstanding the morbid changes and enormous size of the organ, the operation was an easy one, as there were no adhesions to prevent its speedy removal, the latter condition being due to the "gastroptose" position of the stomach. The patient recovered within four weeks after the operation, and was then able to take solid food. A year has now elapsed, and the patient can take any sort of food with perfect comfort. An analysis of the stools show that fibres of flesh food

are present at great quantities at times, but the other food stuffs are completely digested.

HEMATO-MYELIA, OR MULTIPLE HEMORRHAGES IN TYPHOID

Schiff demonstrated several microscopic sections taken from the spinal cord of a patient who had died from typhoid fever. The patient was 19 years of age when he was received into hospital, with all the symptoms of enteric fever, enlarged spleen, roseola, bronchitis and Widal's positive reaction. Four days after his reception he suddenly collapsed with complete motor and sensory paraplegia, commencing a little below the fifth cervical vertebra. The respiration was phenomenal; at each inspiration the abdomen rose like a balloon, while the thorax was lower and narrower than normal, thus demonstrating that the muscles of the chest and abdomen were paralysed, while the phrenic supplying the diaphragm still performed its normal function. Death occurred about the second week of the disease

At the post-mortem no infiltration or effusion was to be found in the brain, and a more careful examination was therefore made of the spinal cord.

Sections were made through the third, fifth, and sixth cervical segments, as well as the fifth, eighth, and ninth of the dorsal region. The latter had small hæmorrhagic infarcts, while the blood-vessels were greatly enlarged. No inflammatory products or signs of inflammation were present, although the membranes were hyperæmic. No micro-organism could be found in the hæmorrhagic centres. Six similar cases are now on record, one of which had specific micro-organisms in the hæmorrhagic foci (Curschmann's case).

From the results in these cases it is usually regarded as a degenerative condition of the blood-vessels as no trace of an inflammatory nature will sustain a phlogistic hypothesis.

CLINICAL FERROMETER.

Jolles exhibited a ferrometer for estimating the total amount of iron in the blood which may properly be designated as a modification of Fleisch's thermometer. It is an instrument with two tubes, one for a solution made from the blood by first evaporating half a cubic centimetre of blood and after calcining it dissolve the ash in sulphate of potassium, hydrochloric acid, and potassiate of rhodiate. The other is for simple water. The total average normal amount of iron in the blood should be 0.0424 per cent.

The Operating Theatres.

WEST LONDON HOSPITAL.

OPERATION FOR RUPTURED STOMACH.-Mr. BIDWELL operated on a boy of six who had been run over by a heavy market van about five hours previously. The patient was suffering from severe shock, the abdomen was distended, breathing being entirely thoracic. There was acute tenderness all over the abdomen, most marked in the epigastric region, and there was complete absence of the normal liver dulness. The patient was put under chloroform, and as the shock from the accident was so great, normal saline solution was injected into the median basilic vein immediately the boy was under the anæsthetic, and was continued during the whole of the operation. The abdomen was opened in the middle line W. TURNER related the after history of the case on

above the umbilicus, and immediately there was a considerable escape of gas and stomach contents, together with some semi-purulent fluid. On examining the stomach a clean-cut rupture about two inches long was found in the centre of the greater curvature of the viscus, the direction of the rupture being vertical, that is to say, in the direction of the circular fibres; and the laceration extended for some distance into the lesser omentum. The stomach contents were sponged out of the peritoneal cavity as rapidly as possible; the wound in the stomach closed in a horizontal direction first by a continuous suture going through all the coats, and secondly by a row of interrupted Halsted sutures. The abdominal cavity was then thoroughly flushed out with normal saline solution, and as the stomach contents had reached into the pelvis, a second opening was made above the pubes for the means of drainage. A drainage tube and a gauze drain were placed down close to the wound in the stomach, the rest of the incision being closed. A second drainage tube was placed through the supra-pubic opening into the recto-vesical pouch. The patient stood the operation well, the pulse being better at the conclusion than at the commencement. Bidwell remarked that the absence of liver dulness was a most important sign in diagnosis of rupture of one of the hollow viscera. This symptom was present in most cases of rupture of the stomach from gastric ulcer, he had also found it in two cases of rupture of an intestinal ulcer, one case being due to tubercle, and the other to typhoid fever. The amount of shock in so young a patient would make an operation absolutely impossible without the injection of normal saline solution: he strongly advocated the plan of relegating this duty to an assistant, and having it continued during the whole of the operation; at any rate in the present case the state of the patient was better at the end than at the beginning of the operation. He pointed out that it was impossible to wash out the peritoneum through the median incision above the umbilicus, but it was absoluely necessary to make a second opening above the pubes, since in this case he had found currants, &c., in the recto-vesical pouch. The time that elapsed between the accident and the operation he said was much to be regretted, since the chances of recovery after rupture of the stomach are directly dependent on the amount of time elapsing between the accident and the operation: in cases operated on within six hours for gastric ulcer nearly all recover, there being no special data with regard to traumatic rupture, which is a very rare but much more serious accident, the accompanying shock rendered it still more urgent that operative measures should undertaken with the least possible delay, as the opening in the viscus is much larger and allows the contents to escape at once in large quantities, in contradistinction to the often mere pin-hole aperture of the rupture through a gastric ulcer.

Twelve hours after the operation the patient again became collapsed, and in spite of saline injections, gradually sank and died. At the post-mortem it was proved that no further extravasation had taken place from the stomach.

WESTMINSTER HOSPITAL.

POINTS OF INTEREST FOLLOWING THE OPERATION REPORTED IN OPERATING THEATRES OF MAY 17th .- Mr.

which he operated for tuberculous disease of the testicle on May 10th. For eight days after the operation the progress of the patient was perfectly satisfactory with the exception of the temperature remaining slightly above normal, varying from 99 degs. to 101 degs. The wound was dressed and the stitches removed on the 8th day; the wound on the left side was found to be completely healed, the one on the right was also healed except at its lowest part, where the drainage tube had been The following night the patient was very restless, and had to be given some morphia, and the next day his mind seemed to wander a little; at times he would suddenly get out of bed, and occasionally was almost maniacal, but in the intervals lay in a semi-somnolent condition, and was only roused with difficulty; he took his food badly, and his pulse was very rapid, feeble and intermittent; the temperature became subnormal and remained so for three days; his general condition being about the same, after which the temperature rose irregularly until his death, which took place 19 days after the operation. The meningitic symptoms only commenced 10 days after the operation, he became more and more drowsy, and, at one time, was very hyperæsthetic all over the body; all his motions, as well as his water, were passed involuntarily, although the quantity of urine appeared to be about normal; there were no other signs of meningitis, and there were no A catheter specimen of urine was obeye symptoms. tained, and found to contain a trace of albumen. At the post-mortem examination extensive tuberculous meningitis and miliary deposits all over both lungs were found; no disease of kidneys, liver, or spleen. The prostate was enlarged, but not definitely tuberculous. The right vesicula seminalis was a caseous tuberculous mass, the left being normal, and the bladder was unaffected. The wounds made at the operation were healed. No other tuberculous deposits were found in the viscera. In commenting on the case Mr. Turner said that the delirium in the commencement and the almost maniacal condition of the patient seemed at first to point to the mania that sometimes follows double castration, but the symptoms came on very late, and the semi-comatose condition appeared to point much more to brain trouble; the urine never gave any indications of any secondary trouble in the kidneys, so that the diagnosis of uræmia was excluded. The patient had tabloids of testicular extract given in the hope that his symptoms might only be caused by the first supposition, but needless to say were useless. There was no doubt from the post-mortem appearances, Mr. Turner remarked, that the tuberculous deposits in the lungs and meninges had been present much longer than the symptoms would lead one to suspect, and that the tuberculous trouble in the testicle was simply one manifestation of a much more generalised disease than was supposed at the time of the operation, the genital tract being apparently the onlypart involved. From these facts he pointed out that it appeared it was not a case of acute tuberculosis following operation for the removal of a tuberculous deposit, but that the effect of the operation was to light up in an acute form the latent trouble in other parts. As mentioned in his remarks after the operation, the ultimate prognosis of these cases is generally bad, owing to kidney affection; the above case giving an instance that tuberculous disease may be present in distant parts without any physical evidence that can be made out.

" SALUS, POPULI SUPREMA LEX."

WEDNESDAY, JUNE 28, 1899.

THE AGED POOR AND LOCAL GOVERN-MENT BOARD INSPECTION.

From time to time the fact is brought home to us that the humanity and mildness of modern manners is in truth the thinnest of social veneers. Nowhere, perhaps, is this conviction more frequently sustained than in the case of the revelations of Poorlaw administration that every now and then startle the conscience of the community. A disclosure of the kind has just been made in the Law Courts. the occasion being a dispute between the guardians of two metropolitan parishes, to wit, St George's - in - the - East and Bethnal Green. It seems that the plaintiff guardians of St. George's agreed to receive into their workhouse a number of paupers from the defendant guardians. The action was to recover a sum of money due for maintenance of the alien paupers, a claim that had been resisted by the Bethnal Green Board on the ground that their paupers had not been humanely and mercifully treated. Upon this issue a long and patient hearing was given to the arguments on both sides, and the evidence disclosed a state of things that one would fain have believed impossible in a so-called civilised and Christian country. The issues placed before the jury by the learned judge were the questions whether harsh and unfeeling conduct had been established against the St. George's authorities. whether the food was bad, and whether the workhouse was mismanaged. The jury returned a verdict for the plaintiffs on the ground that there had not been proof of undue harshness and oppression, but the important question of the food

was not specially mentioned. A technical victory has thus been scored by the St. George's guardians, but we venture to say that their system, as disclosed in the course of this trial, is unworthy of the spirit of the times, and smacks woefully of the bad old days of Bumbledom. What serious defence can be offered for setting old men of ages from sixty to eighty day after day to pick oakum for five or six hours at a stretch? With no backs to their seats, and with fingers bleeding from the task it is no wonder if at least one of them chose rather to go out and face death in the streets. than that, for some trifling offence in punctuality, these old men might be refused breakfast, and then be forced to this senseless labour upon an empty stomach. If that is to be the end of a working life, which has been spent in unceasing and honourable labour, the times must indeed be out of joint. Even in prison administration the fact is being recognised that to keep a man without food is a brutal and unjustifiable punishment. Indeed, the prison life has so far improved as to explain why a certain number of the waifs and strays of society deliberately choose the gaol to the workhouse. With regard to the quality of food given by the St. George's guardians it is to be regretted that the jury did not give a definite finding, but one may hope that in view of the evidence brought forward at the trial that some public inquiry will be made into the matter. Then there is another important phase of the question. As pointed out by the learned judge the Local Government Board inspector who visited the plaintiff's workhouse without notice gave evidence to the effect that he saw nothing to lead him to believe that the inmates were otherwise than properly treated. What are we to infer from that statement? Is the tacit sanction of Mr. Chaplin's Department given to the imposition of the terribly hard labour of oakum picking upon old men during the long hours imposed at St. George's Workhouse? Is the deprivation of the food of the aged a matter of no concern to the Local Government Board? Has the quality of food provided for the inmates of the impeached institution been such as to secure the approval of the Board? Lastly, have all or any of these defects come under the notice of the Local Government Board? If the inspector has reported unfavourably upon the internal administration of that particular workhouse, why has it been left to a neighbouring Board of Guardians to bring the matter forward? In a word, it is desirable to know, in the interests of the public, what part of the machinery is at fault, for something wrong there must assuredly be in a system that allows oakum-picking, and deprivation of food in the case of aged paupers. Does the flaw lie in the inspecting? Is it in the lack of central initiative, or is it in the passive resistance of local authorities? In any case, it is high time that something were done to purge the Poor-law system of its grosser evils in dealing with the aged poor.

PUBLIC BATHS AT HOME AND ABROAD.

THE practice of bathing, it has been observed, if not as old as the hills, is at least as old as man. Nevertheless, except when bathing happens to have been incorporated as one of the rites of the prevailing religion, it has been, from antiquity downwards, but too often more honoured in the breach than in the observance. Habitual and frequent resort to baths seems to be characteristic of a certain stage in the evolution of human civilisation. In most of the civilisations of which history records the rise and fall, public baths formed a prominent feature as they approached their apogee. This was notably the case at Rome, and the intellectual eclipse which followed the destruction of that marvellous civilisation was soon marked by a decline in the matter of personal cleanliness, which persisted in an aggravated degree throughout the dark ages down to comparatively modern times, indeed we are still far behind the Romans in our worship of personal cleanliness. A recent number of the New York Medical Record contains a very interesting article establishing a comparison between various nations in respect of bathing accom. modation, It is gratifying to find that England is far and away ahead of all other nations so far as the provision of wash-houses and baths is concerned. though the Germans, it appears, were the first to inaugurate public municipal baths. In 1794 the Corporation of Liverpool purchased and threw open to the public a swimming bath, and in 1842 opened public baths and wash-houses. The example proved contagious, and at present, of the sixty-five county boroughs with a population of over fifty thousand, only seven are unprovided with public baths. Of the two hundred and fifty smaller boroughs, seventy-four have placed baths at the disposal of the public. In London there are upwards of thirty, in Manchester nine, in Liverpool eight, in Glasgow seven, in Newcastle six, in Birmingham five, while Bristol and Salford possess four each. Germany shows up well for forty out of forty-five German cities with over fifty thousand inhabitants are provided with public baths on the English model. Vienna has eleven baths, but in France and Italy the movement flags. and public baths are much less numerous than elsewhere. In most other European countries bathing accommodation on anything like an adequate scale is conspicuous by its absence. The condition of the United States in this respect is such as to excite some surprise. Coming of British stock, one would have expected to find among the inhabitants of the United States the same enthusiasm on behalf of methodical bathing as in the old country, but we learn that public baths are in use in a very small number of American cities. We gather that in a country containing nearly eighty million inhabitants there are but ten cities that profess to provide bathing accommodation, while in New York State, with its six millions of inhabitants, Buffalo and New York City are the only two cities which have free bathing establishments. It is some satisfaction to learn that New York is awakening to the necessity of multiplying bathing accommoda-

THE MEDICAL PRESS.

comparatively small establishments accessible to the inhabitants of crowded districts than to construct one or two palatial baths, necessarily at a considerable distance from other parts of the city. Even in London much remains to be done in providing free baths for the labouring classes. No pecuniary obstacle ought to be allowed to stand in the way of free indulgence in the pleasures of the bath by working men whose children, at any rate, would be only too delighted to avail themselves thereof during the summer. Not only would they gain in health, but they would thus be enabled to acquire the useful art of swimming. Even more important than the provision of public baths, however, is the provision of bath-rooms in private houses, and in this respect enormous progress has been effected during the last decade or two, more especially in the metropolis. In new houses the rent of which averages from £25 to £30 per annum a bathroom is now the rule, and it is impossible to over estimate the importance of these domestic facilities in spreading the gospel of We hope the day is not far distant cleanliness. when a bathroom will be insisted upon in every house, no matter how humble, on the same footing as a watercloset. From a hygienic point of view one is almost as necessary as the other, and as a measure of national cleanliness, they constitute a safer guide than the proportion of public baths, which are at best but a poor substitute for the domestic provision.

THE ELIMINATION OF THE UNFIT.

THE elimination of the unfit is part of the hypothetical process of the survival of the fittest, and, although perverse human ingenuity appears specially directed to hindering the action of these, raciallyspeaking, salutary processes, there are plenty of examples in nature of the operation of both theoretical laws. The intellectually and physically weak among human beings tend to succumb in the struggle for existence in virtue of their inability to secure an adequate share of food, &c., and their greater proneness to infectious and other maladies and their inherent weakness is accentuated by undernutrition and unhygienic surroundings, which, moreover, operate inimically on their offspring. Syphilitic persons are often sterile, and when fruitful their offspring is stricken with premature decay, which would prove effectual enough were it not for the intervention of medical science. Again, most men who are above the average in point of height or who are intellectually abnormal, whether in excess or in the contrary direction, are less fruitful, when indeed, not absolutely sterile, and their children are usually below the average of physical strength. Nature, however, is very capricious in this matter, for she often renders individuals sterile for reasons which do not strike one as sufficient to merit that penalty, as, for instance, in the case of women who have suffered from gonorrhoea. This is of itself a tolerably benign malady, yet possibly more than any other acquired cause it is productive of

Bumpus, has taken the trouble to examine the dead bodies of sparrows killed during a tempest with the view of determining the conditions which determined their selection. Put briefly, he found that the biggest and the smallest sparrows were those which mostly fell victims to the hurricane. The heaviest birds, by reason of their greater surface, were unable to resist, and, on the other hand, the smallest birds, on account of their less pronounced muscular development, were unable to cope with the strain. He found, moreover, that among the victims were the sparrows with the shortest humeri and the longest femora, in other words, the strain fell most heavily upon the animals which most departed from what we may look upon as the normal type. Putting this as a general principle, no doubt this obtains, even in human beings, though its influence is not usually so brutally expressed. As the average weight of the viscera is about the same, whatever the size of the individual, it follows that the very large man is placed at a disadvantage when compared with him of more moderate dimensions. Expressed in figures the larger man uses up a much larger proportion of his physiological energy in purely vital processes than his more diminutive fellow, and consequently he has a less amount of energy for external consumption, leaving aside the question of the loss of energy entailed by his having to manipulate longer levers in locomotion and in manual exercises. The lesser vitality of the very small, on the other hand, is probably to be ascribed to smaller initial vitality, as evidenced by restricted developmental energy. Some departures from the normal may be advantageous to the individual, and in such cases, according to the doctrine of the survival of the fittest, these aberrations from the normal type tend to be perpetuated, but, on the whole, Nature frowns on all marked aberrations of the kind, and even if of their essence advantageous Nature does not condone such departures, when very pronounced, preferring a gradual ascent. It is particularly in respect of exaggerations of the higher attributes of human beings that Nature shows herself most inexorable. She is willing to overlook insignificant variations in colour and shape, but she cannot pardon too exaggerated a mental development. and accordingly she strikes the offspring of the unduly intellectual with a decadence as pronounced in its way as the genius of the parent was excessive, judged by the normal standard. On the whole this is comforting, because if the offspring of the highly gifted inherited the talent of their parental stock, plus the advantages accruing from their experience of the world, the ordinary individual, who in the aggregate makes up the masses, would stand no chance, and would inevitably become the serf and bondman of these more fortunate and gifted persons.

An outbreak of malarial fever is reported to have occurred at the Hague, among the victims, according to the reports, being several members of the Peace Conference.

Rotes on Current Topics.

Cerebro-Spinal Fever.

THE subject of cerebro-spinal fever discussed by Professor W. Osler, in the Cavendish Lecture which we published last week, has a special interest in this country, inasmuch as it is an almost unknown disease. It occurs with such rarity that to the majority of English practitioners it is known only by name. Epidemic cerebro - spinal meningitis, as cerebrospinal fever is otherwise called, is, however, by no means a disease with which an intimate acquaintance is desirable. Our ignorance of its clinical features, owing to its rarity in this country is a matter upon which we may congratulate ourselves, for whatever the precise etiology of the malady may be, and however much many points concerning it are involved in obscurity, there is nevertheless one definite feature belonging to it, and that is the high mortality associated with its occurrence. Thus in a recent epidemic at Boston, out of 111 cases 76 died, making a mortality of 68.5 per cent., a mortality which scarcely any known fever attains. Thus it is one of the most fatal of all acute diseases, although, fortunately, no fever attacks so few individuals in a community during its periods of prevalence. But another bad feature in connection with the malady is the hopelessness of treatment. Osler admits that in his series of cases no special drugs were employed. Relief from pain was sought by the free administration of morphia, and ice sponging was resorted to whenever the temperature rose above 102.5 F. Again a trial has been made of laminectomy with a view to the withdrawal of cerebro-spinal fluid, but further experience is required of this method of treatment before a definite statement, as to its utility or otherwise, can be pronounced. Perhaps, however to the scientific physician the interest of cerebro-spinal fever is centred in its bacteriology. This aspect of the disease has only recently been investigated, but it is now agreed that the specific cause of the malady is an organism known variously as the meningo-coccus and the diplo-coccus intracellularis meningitidis.

A Medical Action for Slander.

In an action for slander brought by one medical man against another which was tried last week before Mr. Justice Ridley a curious point in law was brought into prominence. The defendant was alleged to have told his assistant that the reason why he bad been called in to attend a particular patient was because the doctor in attendance was on one occasion under the influence of drink. The case presented no particular interest, being merely a squabble between two neighbouring practitioners, but as privilege was pleaded, the judge laid it down that while a doctor was privileged in communicating to his assistant the nature of the disease from which a patient was suffering, he was not privileged to tell his assistant why he had been called in over the head of another practitioner. Thereupon the defendant withdrew his

was settled. allegation and the case main, though, the point is rather fine practical use, we are disposed to concede that the judge's pronouncement is reasonable. It is obviously necessary that a practitioner should place his assistant in possession of all details that may be necessary to his position, but it cannot be said that the information concerning the reasons which had led to his being called in on this occasion were of this nature. We trust the lesson will not be thrown away, that medical men in talking of their brethren should introduce caution if not charity into their utterances. We have no sympathy with anyone who deliberately circulates reports concerning a rival calculated to damage the latter in public esteem, and we should scrutinise very closely the plea of privilege when pleaded as a bar to an action for slander.

Holiday Leave for Poor-Law Doctors.

WE think it right to warn all Irish Poor-law Medical Officers that the boon of a month's holiday in each year provided for them by Article 28 of the new Dispensary Regulations is liable to be rendered nugatory by the interpretation of the rule by the Guardians. We observe that the Belfast Guardians have made a fixed rule that doctors shall not have more than a fortnight's holiday leave and apothecaries not more than seven days. This rule is conformable to the Dispensary Regulation which declares that the annual vacation shall not exceed four Furthermore, before going away, the weeks. doctor must "nominate a duly qualified practitioner who undertakes to perform the duties of temporary medical officer at a rate of remuneration to be stated (? by whom), and until the Local Government Board express their approval of the arrange ment." If the word "stated" means, as it obviously does, stated by the guardians, it will be open to any board to prevent any medical officer from obtaining any leave by fixing such remuneration for his locum tenens as no one will accept. We know already of one case in which this has been done, and it seems likely that the doctor there will have to do without holiday.

County v. City in Asylum Management.

A MEETING of the Derry Asylum Committee a few days ago was made the occasion of expressing strong dissatisfaction on the part of district councils, especially Derry, because it has no representative on the Committee of Management of The position of Dr. O'Kane in the the Asylum. matter was thus expressed:—"He objected to the idea of any antagonism between the city and the county in the matter, because he thought the people of the county should be just as much interested in the management of the Asylum as the people of the city. He wished to say, so far as the city was concerned, there was no antagonism towards the county, and he hoped they would all work harmoniously together for their common good, and for the proper care of the lunatics." The discussion is but a repeat of many others which are agitating the country elsewhere. The cry for local parochial government is being more and more listened to: and there is danger of it becoming too much a question of practical politics Of the Derry representatives we know nothing; but ambition for power in asylum management is being shown by men who each has his own axe to grind, and the management of some asylums seems to be run more in the interest of the people's representatives than the patients. Noblesse oblige is well illustrated in the conduct of the better class of representatives, and they are usually county gentlemen. The idea of local government by the parish units combined, for the benefit of the county and city as a whole, is a beautiful conception, but it won't work. In some parts of the kingdom-indeed, in many parts—the people's representatives are often not up to the average mental calibre and morale of the people themselves. All this notwithstanding, the tone of the discussion referred to in this case was calm and judicial, and probably the city is quite equal to the county if its representatives are men of education and good standing.

The Local Government Board and the St. Olave's Vestry.

A FORTNIGHT ago we mentioned the fact that the Metropolitan Vestry of St. Olave's had suspended their Medical Officer of Health, Dr. Bond. immediate cause of this extreme step was the action of the official in question with regard to the removal of bodies from the parish church. It appears that such a step could not legally be taken without the concurrence of the Ecclesiastical Commissioners, the Bishop of the Diocese, and the District Medical Officer of Health. Acting upon his own interpretation of the Act Dr. Bond helped in the removal of the remains. A great outcry was thereupon raised in the Vestry, and Dr. Bond was suspended on the ground that the Act really meant the sanitary authority, although it specifically mentioned the Medical Officer of Health. That view has not been sanctioned by the Local Government Board, which has refused to endorse Dr. Bond's suspension, and has sent a sharp intimation to the St. Olave's Vestry that the medical officer was authorised to act individually without consulting the Vestry. This decisive support of a medical officer by the central authority will come as a welcome harbinger of the future to many a harassed medical officer of health.

A New Form of Milk Adulteration.

Some facts have recently come to light which show that an entirely new form of milk adulteration is now being adopted. A circular came into the hands of a milk vendor in a large provincial town from a firm purporting to be manufacturers of "artificial milk," and offering certain terms to the vendor by which he could advantageously purchase some of the commodity for admixture with his milk, and so increase his profits. Inquiry showed that the use of the artificial product could be so arranged that one churn in six would consist of the spurious article. Again, it was stated that many large milk-sellers

had added greatly to their profits by adopting the suggestion of the manufacturers in question. But when the latter were requested to give the names of their customers as references, the reply was that no such request could be complied with, as it would be against the interests of the firm to do so. Thus, here was a case in which a respectable tradesman was directly invited to embark upon a fraudulent practice, and to do that which he was given to understand was being largely adopted by others in his own Fortunately, however, he made, line of business. instead, the matter public, and declined to be a party to the fraudulent transaction. The worst feature in the case is that the detection of the spurious milk by analysis has not, so far, brought the offenders within the clutches of the law. After this disclosure, however, the authorities concerned in protecting our food supplies from adulteration should make a special feature of analysing the milk within their respective districts.

The Sale of Quack Medicines.

MR. BRAXTON HICKS, the coroner, seldom loses an opportunity of giving sound advice, when occasion arises, to those in his court who require it. A few days ago, for example, he read the quack-nostrumbuying public an excellent homily upon their folly and want of sense. The text was supplied by an inquest which he held concerning the death of a journeyman tailor, who, a sufferer from epilepsy, wasted his money at the rate of eleven shillings a bottle upon a quack concoction. The medical evidence showed that this concoction consisted of chloroform water, coloured with burnt sugar, containing a few grains of bromide of potassium; and that its inclusive value, with the Government stamp, sixpence. could not have been more than The jury were so impressed with these revelations and the coroner's remarks, that they added a rider to their verdict to the effect "that they considered that the attention of the proper authorities should be called to the gross fraud perpetrated upon the public by sale of these mixtures at exorbitant prices.' We trust that this pronouncement will have the effect of infusing some sense into those easily imposed upon persons who so readily accept as truth the specious fables of cures contained in the announcements of the purveyors of quack nostrums. If such persons could only be induced to realise for a moment that the quack nostrum vendor would be quite unable to pay for his voluminous advertisements unless he overcharged the public for his wares, they would then perhaps be able to understand that it would be much more economical to obtain their medicines through the usual and regular channels.

Tuberculosis and Climate.

In almost every county in England steps are being taken to found sanatoria for persons suffering from tuberculosis, and in this connection the curious poi t has arisen that such sanatoria are about to be built in localities where the disease is extensively prevalent. For example, it has been asserted that while

Rothbury in Northumberland-famous as the home of Lord Armstrong-is now becoming a favourite resort of consumptives, who derive great benefit from the locality, the native population of the district themselves frequently fall victims to the disease. There is doubtless a good deal of truth in this statement. In some Northumbrian villages, especially upon the coast, the majority of the population are tuberculous. This is partly to be accounted for by the fact that inter-marriage to a large extent occurs among the resident families, thus a strongly inherited predisposition to tuberculosis becomes prevalent throughout the district; as is well known girls who come of a tuberculous stock are often beautiful specimens of maidenly comeliness, and thus the village swains-who may be their cousinsearly become enamoured, and marriages soon follow which, in the light of present knowledge, should not take place at all. By this means tuberculosis can readily become rife in a district, as has oftentimes been proved. Many of the children. born of such parents, die of tuberculous meningitis. and those that survive childhood fall early victims to phthisis. There is another point of considerable interest in relation to this subject, and that is the wariness exhibited by Nature in safe-guarding her interests in regard to tuberculous persons. Hazarding some guesses, it may be that tuberculous girls are often naturally beautiful and prolific after marriage because, unless this were so, the ravages of the disease would seriously affect the reproduction of the species. In short, in order to make up for the destructive effects of tuberculosis upon life, Nature seems to have made special arrangements for ensuring a reproduction of the species so as to counteract the loss.

A Malarial Investigation Expedition.

THE Liverpool School of Tropical Diseases is forging ahead so rapidly in its undertaking, that its promoters are deserving of much praise for the spirited policy which they are pursuing. In the first place they have agreed to receive from the Colonial Nursing Association in London three nurses for special training in the tropical diseases wards at the expense of the school. Furthermore they have definitely decided to despatch a special expedition for the pur pose of investigating the causes of malaria and other indigenous diseases on the West Coast of Africa. The expedition will be under the direction of Major Ross, I.M.S., the recently appointed lecturer, and Mr. Annett, the demonstrator, to the Liverpool School. As soon as the arrangements for the expedition are completed, it will start for Sierra Leone if possible early in August, when the malarial season is at its height and the conditions are most fayourable for research. Major Ross will, in his researches upon the West Coast, especially inquire into his theory which attributes malaria to the bites of a certain species of mosquito. It is this theory which has received so much acceptance from authorities upon the subject, and the results of these investigations will naturally be looked forward to with considerable interest

However, nothing could be more calculated to add to the practical value of the Liverpool School of Tropical Diseases than that two of its instructors should proceed to the very spot where malarial fever is most rife in order to perfect their knowledge of the subject by personal, scientific, and practical investigation. The success of such a school is at onceassured if this is the kind of enterprising policy which its promoters intend to pursue.

Coroners and Post-mortem Examinations.

A CASE which occurred before the Sheffield city coroner last week illustrated a point in coroner's law to which attention may be usefully directed. A child fell and injured its head, and after having been treated for some days as an out-patient at the Sheffield Royal Hospital was admitted into the Institution, suffering from symptoms of which she ultimately died. The house physician, with the consent of the mother, made a post-mortem examination of the body, and found that the cause of death was tuberculous meningitis. At the inquest, which was held in due course, the above facts transpired, and the medical witness was taken to task by the coroner for having performed a post-mortem examination without having first obtained official sanction to do so. The law concerning this detail, of course, is very explicit. The body of a person whose death has occurred through violence is absolutely under the control of a coroner; no one else possesses any rights over it; where it lies there it must remain, untouched and uninterfered with, until it pleases the coroner to issue instructions respecting it. Resident medical officers, therefore, in public institutions should not omit to bear these facts in mind for their guidance in all inquest cases.

The Strawberry Cure.

On the authority of Linnæus, the treatment of gout by the free ingestion of strawberries has been resuscitated, and though we are not yet in the dead season it has been taken up by the daily press and run for all it is worth. In the biographical notes written by Linnæus himself, and translated into-English by Joseph Trapp in 1794, we find mention of the fact that he succeeded in curing himself promptly of a severe attack of sciatica by eating profusely of strawberries on the advice of his wife, who was opposed to his taking opium for the relief of the pain. A return of the painful manifestation during the succeeding year also proved amenable to the The translator adds significantly that treatment. "Linnæus died soon after, and so the experiment Absit omen. After the grape cure the ceased." strawberry cure. The treatment, which is perfectly rational, provided too much importance be not attached thereto, has the advantage of being within the reach of the humblest, at any rate of those whose symptoms happen to fall due during the strawberry season. There are probably few among the well-to-do who would not be the better for an occasional course of "strawberry treatment," which implies a holiday from the usual too highly nutritious and stimulating diet

and, presumably, a rest from the excitement and worry of their daily avocations, In some, no doubt, the pips contained in this luscious fruit would determine more or less intestinal discomfort possibly culminating in appendicitis, but this is a contingency which must be faced in exchange for the blessed hope of getting rid of a troublesome tendency. Accurate clinical details of the effects of the "cure' are wanting, but these we imagine would compare to some extent with those of a "cure" at one or other of the famous watering places where a strict regimen always occupies a prominent position.

The Perils of Patent Medicine Trading.

If we may judge by the financial condition of some of the best known and most successful quack medicine companies, as reported in the Chemist and Druggist, the public taste for these concoctions is very fickle. The first such company to come to grief was the American. Hop Bitters Company. The vendor who made the business took, in 1886, £60,000 in cash and £25,000 in debentures for his interest. The first year paid £10 per cent., the second year nothing, and in 1892 the whole affair was sold by auction for £3,000. "Sequah" came next. He sold himself for £150,000 in cash and £100,000 in shares. The company paid 14 per cent. first year, showed a loss of £25,000 second year, and was wound up without a shilling in 1895. Then came Warner's Safe Cure. The vendor took £446,000 in cash and £260,000 in shares. The first two years paid 20 per cent., the third year 10 per cent, and no dividend has been paid to the ordinary holders for five years. Last comes Mother Siegel (White and Company), This concern was practically altogether in the hands of Mr. White, the other directors being-by their own confession—entirely ignorant and confiding. It paid 10 per cent. in 1898, but on Mr. White's death a month ago, it was found that there was a deficit of £40,000. It is said to be still doing a large business, though the profits have fallen in one year from £90,000 to £50,000. When the business was converted, the vendors took £960,000, of which £626,000 was in hard savings.

An Oyster-Typhoid Tragedy.

THE indictment against the oyster as an article of food attained crushing proportions in the special report upon the subject issued a couple of years ago by the Local Government Board. The upshot of the agitation was an enormous falling off in the consumption of this dainty and nutritious shellfish. Since then folk have plucked up heart again and returned to some extent to this favourite article of food, with the result that many fresh fatalities have been reported. One of the latest comes from Hove, where a town councillor has died of enteric fever contracted by eating oysters. It seems that a few weeks ago he formed one of an oyster supper party, and on returning home complained of pains in his back. At least four others who supped with him have been taken ill, but it is interesting to note that one only is reported definitely to b suffering from the

specific infection. It is to be hoped that the source of the oysters will be traced, in order that the particular source of this disaster may be at once rooted up from the midst of the community. In the face of the Government report, it seems hardly credible that local bodies and oyster merchants should have failed to set their culture and storage beds in sanitary order. Yet we believe that in many instances nothing whatever has been done towards purifying the foul environment of the oysters. The tragedy of the Hove incident should do much to strengthen the demand for immediate oyster legislation by the Government. For that matter, however, these tragedies have been going on continuously, only they have not received the prominence bestowed on the unfortunate occurrence at Hove.

The Thirteenth International Congress of Medicine.

WE have been favoured by Mr. D'Arcy Power with an advance copy of the official programme of the Thirteenth International Medical Congress, which will be held at Paris in 1900, between August 2nd and 9th, under the presidency of Prof. Lannelongue. There will be five sections, (1) biological sciences, (2) medical sciences, (3) surgical sciences, (4) obstetrics and gynæcology, and (5) public medicine. The English Secretaries are, Dr. A. E. Garrod, Mr. D'Arcy Power, and Dr. Keser. As the Congress will be held coincidently with the International Exhibition, and at a date which will correspond to the maximum number of visitors, it is necessary to point out that those who propose to attend will do well to give early notice of their intention, or they may experience considerable difficulty in securing hotel accommodation. We are disposed to question the wisdom, from a scientific point of view, of holding the Congress amid the bustle of a great exhibition which cannot but detract from its success in all save a numerical respect. Who will be likely to sit out a long paper in a hot room when the danse du ventre is on view round the corner, and the myriad attractions of an exhibition in the modern Babylon spread a seductive net over all?

Joint-Stock Doctoring.

Some weeks since we called attention to a company of speculators which had been organised in Dublin under the title of "Dr. Bland, Limited," to "carry on the profession of medical doctors, physicians, surgeons, apothecaries, pharmaceutical chemists, dentists, midwives, &c." All the members of the syndicate were unqualified with the exception of two medical practitioners, and we ventured to warn these gentlemen that their association with the practice of such a company might render them liable to the attentions of the General Medical Council for "covering" the practice of unqualified persons. We note with satisfaction that one of the medical practitioners and one registered pharmacist who had joined the concern have taken our hint and withdrawn from the dangerous position.

Medical Organisation at Enfield.

THE practitioners at Enfield, to the number of sixteen, have joined hands in the determination to refuse to attend persons belonging to any medical aid society, and an advertisement has been published to the effect that the practitioners in question, having resolved to have nothing to do with medical aid societies, have formed a doctors' club for attendance on families whose income is under £2 a week. Hitherto most combinations of the kind have broken down owing to the readiness of outside practitioners to undertake the work, but in view of the recent pronouncement of the General Medical Council, it may be anticipated that less scrupulous men will hesitate before rushing in where angels fear to tread.

Auto-Auscultation in Incipient Tuberculosis,

ATTENTION has been called by a French observer to the fact that persons with incipient tuberculosis not perceptible to ordinary auscultation often experience, when talking loudly, a sensation of local vibration over a given area of the thorax corresponding to a zone of partially solidified subjacent lung. In some the sensation amounts to positive discomfort, but more frequently it is not perceived by the patient until his attention has been directed thereto by the physician. The point is worth noting, though in all probability a degree of infiltration which would expose the patient to this sensation of localised vibration would be sufficient to attract attention at the hands of the examining physician by the ordinary methods of physical investigation.

Bicycling in Diabetes.

THE question of exercise for diabetic patients is one requiring careful consideration, the more so as the imperfect nutrition from which many of them suffer indisposes them to active pursuits. According to Albu methodical muscular exertion, such as that of cycling, is a therapeutical factor hardly second in importance to the regulation of the diet. It has the advantage moreover of being more readily applied than the latter, which entails a degree of patience and perseverance not always at the command of the sufferers. It is hardly necessary to add that the effects of the exercise should be very carefully scrutinised at first, not only in respect of the urinary sugar, which should be estimated both qualitatively and quantitatively, but also in view of its effects on the renal function.

The Union Drug Analyst.

THE Local Government Board for Ireland has made it understood that it will not sanction the appointment to the post of analyst to an Irish union of a simple pharmaceutical chemist. They say that candidates must "have considerable experience of the analysis of drugs, and must have obtained (by examination) a diploma in pharmacy, materia medica, and volumetric examination of drugs—from recognised examining body,"

The Late Mr. Lawson Tait and the Anti-Vivisectionists.

The anti-vivisectionists have been making all possible capital cut of a passage anent experiments on living animals contained in the last communication from the late Mr. Lawson Tait which appeared in our columns. Mr. Tait's views on the subject are well known, and the anti-vivisectionists are welcome to make the best use they can of the utterances of this eminent surgeon whose fame in years to come will be based, not on the fads from which he, eminent though he was, was not exempt, but on the solid surgical achievements the success whereof was largely due to the recognition of principles and practices obtained by patient and painstaking researches entailing the sacrifice of much animal life.

One Shilling a Week for the Doctor.

The guardians of the Cahirciveen Union have, we rejoice to say, been mulcted by Judge Shaw with a decree and costs. Dr. Walker, of Glenbeigh, having been summoned to give evidence at the assizes, gave due notice that he must be absent from his district, and recommended his son, naming the fee of £1 ls. a day. The duty was performed, and the guardians then voted the munificent sum of ls. for the whole period. As we have said they were ignominiously defeated, and we hope that the solicitors on both sides will not stint themselves in their costs.

Small-Pox Epidemic at Hull.

It is satisfactory to note that the epidemic of small-pox at Hull has been circumscribed, the report of the Medical Officer of Health testifying to sixty-one cases with thirteen deaths. The cases comprised both vaccinated and unvaccinated persons, but of the former only four out of forty-five succumbed, i.e., one in twelve, while of the unvaccinated, nine out of sixteen died. i.e., more than one half. No doubt if the date of vaccination were taken into account the protection afforded by vaccination would be even more apparent, for not one of the fatal cases is reported to have taken place in a revaccinated person.

The Practice of Medicine in Italy.

THE practice of medicine in Italy, so far as foreigners—that is, Englishmen and others—are concerned, is limited to attendance upon persons of their own nationality. The Italian Government have issued a circular letter to all their Ambassadors to this effect, and at the same time have stated that, with this exception, it is forbidden to anyone to practise medicine generally in Italy unless he possesses an Italian medical qualification.

An Unqualified Assistant's Libel Action.

An absurd action was tried in the Queen's Bench Division last week in which an unqualified assistant, described as an Asiatic, sought to recover damages from a number of daily papers for having published reports of a county court suit brought by the plaintiff, against his erstwhile principal for a sum of money

alleged to be due. The circumstances as reported were extremely amusing, but ultimately the jury stopped the case on the ground that there was no libel.

The Annual Meeting of the Irish Medical Association.

This congress of the members of the Association assembled in Cork on the 20th inst. under the presidency of Dr. Hobart. The profession in that city had made preparations to receive and hospitably entertain their visitors, and were entirely successful in securing the conduct of important business and the comfort and enjoyment of the members. A banquet was held, at which most of the county magnates were present, and on the succeeding day the visitors were taken by steamer to Queenstown, and round the harbour to view the regatta, and were entertained to luncheon on board. We regret that the great pressure on our space for the accommodation of our half-yearly index and other important matters, obliges us to postpone publication both of the report of the meeting and the annual report of the Council.

PERSONAL.

SUBGEON-GENERAL A. F. CHURCHILL, M.B., of the Army Medical Staff, has been placed on retired pay.

LIEUT. A. B. MACCAETHY, M.B., has resigned his Commission in the Royal Army Medical Corps; and Surgeon Captain C. A. MacMunn, M.D., has been promoted to Surgeon-Major.

THE DUKE AND DUCHESS OF YORK opened four new homes on Saturday last at the colony established by the National Society for the Employment of Epileptics, at Chalfont, Bucks, of which his Royal Highness is president,

Dr. G. E. Shuttleworth and Miss F. May Dickinson Berry, M.D., B.S. Lond., have been reappointed by the London School Board for a second year to examine defective children and children alleged to be defective, who have been recommended for special instruction, and to perform cognate work in the blind and deaf centres.

INSPECTOR-GENERAL HENRY MACDONNEL, C.B., of the Royal Navy Medical Department, who has been placed on the retired list after thirty years' service, was on board the Invincible at the bombardment of Alexandria in 1882. He was made a Companion of the Order of the Bath on the occasion of the Diamond Jubilee in 1897

OUR Manchester correspondent informs us that honorary degrees of the Victoria University are to be conferred upon Professor Clifford Allbutt, M.D., F.R.S.; Professor C. H. Herford; Dr. J. E. Schunck, and Mrs. Henry Sidgwick on Saturday next. Mrs. Sidgwick will have the distinction of being the first lady to receive the henorary degree of the Victoria University.

DE. RICHARD GARNETT, C.B., late Keeper of Printed Books at the British Museum, was presented on Friday last with his portrait in oils, painted by the Hon. John Collier, together with a gift of forty-seven volumes of works of reference, subscribers to which included librarians from all over the United Kingdom, Canada, France, Germany, and the United States.

Scotland.

[FROM OUR OWN CORRESPONDENT.]

GLASGOW UNIVERSITY.—The final examinations now completed have not terminated to the unqualified satisfaction of candidates. Among many causes for grumbling on the part of students is in the outset the multiplicity of examiners Usually there are four in surgery, and in medicine this year no less than six different examiners, each of whom it is reported has little points to which he is specially partial, and which may be classed under the term "fads," but he nevertheless expects the unfortunate candidate to know all about them. Should a ca didate express to examiner A. the method of B. in performing an operation which does not tally with A.'s fad for the same operation and vice versa, the danger to the said candidate is self-evident. By this unfortunate state of matters, many good and hard-working students have come down and been referred back, especially in surgery.

QUEEN MARGARET COLLEGE.—At the recent final examinations the women students have come out well, and in every branch pressing the males very hard. Among Queen Margaret students a scheme has been recently brought to their notice which is being organised by a committee of medical women practising in Scotland, and which proposes to establish a fund in commemoration of the efforts of Dr. Sophia Les Blacke, who is now retiring, and to whose work the satisfactory position of women in the profession is largely due. If funds are forthcoming, the present idea is to offer periodically a post-graduate scholarship or something of that nature.

HORSE-PLAY AT THE EDINBURGH ROYAL INFIRMARY. The resident physicians and surgeons have recently been making themselves slightly ridiculous. "Ragging" of bedroems and other more or less elaborate practical jokes are an old tradition, and, as a rule, no harm comes of it. This summer, unfortunately, the fooling has not been taken as it was meant, or, say the victims, was carried to an undue extreme. Be this as it may, the friction became so excessive that certain members of the residency thought right to lay the matter before the authorities a few days ago, and a thorough inquiry is being instituted. It seems to us that, in itself, such practical joking—even if it does reduce a man to vacating his room for a night or two-is of little consequence, but what the residents do not realise is the amount of harm to which the publicity of their actions—harmless enough in themselves - may give rise. The credit of an hospital, in more ways than one, depends on their behaviour; it is with them that the public come most frequently and directly in contact, and (though it is not for one moment suggested that the patients can or do suffer in any way on account of rows in the residency) surely a very little common sense might tell the men that to act in such a way as periodically to yield "copy" to the newspapers is neither seemly nor calculated to inspire the public with confidence.

Obituary.

DR. CAHILL, OF BALLYNACARGY.

The above well-known and respected member of the medical profession died at his residence, Ballynacargy, on Sunday, the 18th inst., at the age of 75 years. Dr. Cahill commenced professional life in the district more than half a century ago, and for many years had a lucrative and extensive practice in the counties of Westmeath and Longford. He was an honorary surgeon to the county infirmary, and as well as being a magistrate for the co. Westmeath, was for a time member of the Council of the Irish Medical Association.

Of a retiring and unobtrusive manner, there were few physicians in rural practice in Ireland who so fully possessed the confidence of the community as a well-informed and conscientious practitioner; kind, urbane, and genial to all, he passed away mourned, beloved, and respected by those among whom he lived and laboured so long.

DR. WILLIAM McGILL, OF GLASGOW.

Dr. McGill, who died on the 17th inst., was for over forty years medical officer to the police force in Glasgow. which post he held and discharged its duties until 1896, when he ceased from active duty, and was allowed a retiring allowance. He was a Licentiate of the Faculty of Physicians and Surgeons, Glasgow, 1848, and of the College ef Physicians, Edinburgh, 1859, and M.D. of Glasgow University, 1867. Dr. McGill was of an exceedingly kindly disposition, discharging his duties during his long term of service with satisfaction both to the members of the force and to the authorities. At the time of his death he had reached the ripe age of eighty-two years.

Correspondence,

We do not hold ourselves responsible for the opinions of our correspondents.

NORDRACH AND FALKENSTEIN.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—In the Medical Press and Circular for May 31st appears an editorial article entitled, "The Rival Systems for the Sanatorial Cure of Phthisis."

The writer refers in the first place to "the wordy warfare waged between the apostles and their disciples of the two schools, viz., Falkenstein and Nordrach; Falkenstein with its apostle Dettweiler, and Nordrach boasting Walther as its prophet."

In reference to this I would merely remark that Dr. Dettweiler has never written a word against Nordrach, nor has Dr. Walther ever published a single line, either about his own sanatorium or any other, except once, to contradict a sapient visitor who declared that there were no windows in his institution. On the contrary, I have never heard Dr. Walther speak of Dr. Dettweiler except in terms of admiration; and I know he regards the deficiences of Falkenstein as being due to deviations from the original spirit and intention of Dettweiler himself.

This article is, however, more understandable when one remembers that visitors to Nordrach seem to consider a twenty minutes' stay in the place sufficient ground for writing an authoritative criticism upon Dr. Walther's system of treatment; so much so that they are ironically called by patients "the twenty minutes' doctors."

To quote again from the Medical Press and Circular article. Referring to a Nordrach patient, the writer says:—"If unwilling to sleep with a wide-open window, the window is removed."

With regard to this statement, I may observe that I have lived a year and a half at Nordrach, and can absolutely don't have a lived a year.

lutely deny that such a thing is ever done.

Again, the writer says that "The Nordrach system aims at individual medical control, and limits the number of inmates; but even this has a drawback, for it is seldom possible to install a resident expert laryngologist because of the expense; and even the Nordrach treatment requires, it appears, some local assistance in laryngeal cases. It is extremely difficult to find out the truth as to laryngeal cases of consumption in sanatoria."

Dr. Walther has never attempted to install a resident lary ngologist, for the very good reason that he was himself an expert laryngologist in Frankfort before the illness of a consumptive relative decided him to give up his practice and undertake the treatment of consumption

The writer goes on to say, "We believe that such patients—i.e., laryngeal cases are not personæ gratæ at Nordrach."

I am in a position to state that Dr. Walther usually knows nothing about his patients until they arrive at Nordrach, that there is no selection of cases such as obtains in most of the other German sanatoria, that numbers of laryngeal cases are treated at Nordrach, and that there are people now in England who, having suffered from laryngeal tuberculosis, have been cured at Nordrach, remain well, and are even able to sing.

But the most astonishing statement yet remains to be cited. The writer, in speaking of the methods of sanatoria of the Falkenstein type as compared with Nordrach, says, "There is no doubt that both are right in so far as they are severally adapted for various different types of patients; one type of patient is benefited by the milder regime (i.e., Falkenstein), injured by the harsher, and vice versa." Very plausible, but not correct. Has the writer a single tittle of evidence to support this statement? I trow not. Now I have treated patients, both English and German, under Dr. Walther, at Nordrach, patients coming from other German sanatoria conducted on the same lines as Falkenstein, and I can refer the writer to people in Frankfort if he likes, who, after trying the sanatorium treatment inculcated by Dettweiler for many months, failed to make progress; nay, were fast pursuing the downward path and who were cured at Nordrach, and now follow their ordinary avocations in good health.

Can the writer of the article adduce a solitary instance in which a Nordrach patient, failing to improve there, has gone to some other sanatorium and made a recovery? I know he cannot, and I know that the Nordrach treatment is the best system ever devised for bringing about the arrest of pulmonary tuberculosis, and that if that system fails there is then no other means known to us at present which has the slightest chance of bringing about the desired result.

I think it would be well if would-be critics of Dr. Walther and his system would first take the trouble to verify their facts.

I am, Sir, yours truly, (Signed) R. MANDER SMYTH, M.D.Lond.

[No better evidence could be afferded of the exparte views of an adherent to one of the systems referred to than by Dr. Mander Smith's letter. No one, forsooth, has ever been benefitted by any other system after having failed to respond to his own special pat! We know personally of several cases. Nor are Nordrach and Falkenstein the only institutions, though they may be the earliest and most famous in which the systems are carried out. As Dettweiter is still the consulting physician at Falkenstein, and constantly visiting the sanatorium, it is to be presumed that any change in the routine there has his sanction and approval. Dr. Smith "knows" that the Nordrach system "is the best." Just so, that is the point we were complaining of.—ED.]

Medical Rews.

Messrs. Burroughs, Wellcome, and Co.

HAVE during the past few days opened new chemical research laboratories at King Street, Snow Hill, with Dr. F. B. Power as director of a large staff of scientific workers. The increasing demand for the serums of this firm has also necessitated increased accommodation for their manufacture, to insure which they have acquired the Brockwell Hall estate at Herne Hill, where the fine old mansion is in course of reconstruction in order to adapt it to purposes foreign to its original designer, whilst the extensive paddock will form a valuable adjunct for rearing and keeping the animals necessary for serum culture. But whilst keeping pace with the exigencies of business they have not neglected the health and enjoyment of their workpeople. Were it not for the fact that the principal—Mr. Wellcome—has not yet reached middle age, one might not inaptly describe him as Patrix pictatis imago, inasmuch as on Saturday last he presented a large park, with club and institute, to his employées, who now number more than 800 of both sexes (including a large number of professional scientific workers), in order to promote harmony and social intercourse amongst them, to encourage mental and physical recreation by means of musical, literary, and other entertainments, educational classes and lec-

scientific and technical subjects, and by providing the space and opportunity for indulgence in athletics, field sports, and games. The club and grounds are close to the factory at Dartford, and on Saturday the donor generously gave hospitality to about 1,000 people, including guests, among whom were several members of the learned professions. The day was devoted to sports and recreation of every conceivable kind, finishing up with the presentation of prizes by Mrs. A. Chune Fletcher, the illumination of grounds, lake, and river, and a brilliant pyrotechnic display.

Abscess, or Aneurysm?

An interesting action was tried at the Sunderland County Court last week, when one Smith, a labourer, claimed damages from Mr. Robert John Burns, a Poorlaw medical officer, for having opened an aneurysm, which he had mistaken for an abscess, in spite of the protests of the plaintiff. It transpired that the plaintiff had been an in-patient at the Infirmary for this very aneurysm, but had left of his own free will. Hethen obtained an order, and Mr. Burns attended him in consequence. The plaintiff does not appear to have told the defendant the nature of the lesion as diagnosed at the infirmary, and without due reflection Mr. Burns made an incision, but promptly discovered his mistake, and after some delay steps were taken to arrest the hamorrhage. The allegations of inebriety made by the plaintiff against the doctor were shown to be devoid of foundation, and after it had been explained to the jury how easy it was to mistake an aneurysm for an abscess, an error for which there are numerous illustrious precedents, they returned a verdict in favour of the defendant.

Death From Tetanus.

A DEATH from tetanus was the subject of an inquest in East London last week, the victim being a blacksmith, set. 51. The symptoms had developed some days after an injury caused by a fall from a cart, and it was only on the tenth day that he was sent to the hospital, where he shortly after died.

Carbolic Acid Poisoning.

In reply to Sir John Leng, the Home Secretary admitted the frequency with which death occurred from the accidental and intentional ingestion of carbolic acid, adding that when some years ago the Pharmaceutical Society petitioned the Privy Council to comprise the acid in the schedule of poisons it was considered that the gain to the public would not be commensurate with the inconveniences of such restrictions. He admitted that it was scheduled as a poison in Ireland, but that was by a special Act. He concluded by stating that the Privy Council were prepared to consider the desira-bility of dealing with the subject, but could only do so on representations from the Pharmaceutical Society. As these representations will presumably be forthcoming it may be that we are within reach of this much needed step, though in view of the procrastinating policy of the Privy Council on this point in the past we dare not express too sanguine a view.

Death Under Chloroform.

Another death under the so-called "open" method of chloroform admini-tration is reported from Edin-burgh, where a labouring man died shortly after the performance of an operation for which the anæsthetic had been given.

Association of British Postal Medical Officers.

THE annual dinner of this association took place at the Whitehall Rooms, Hotel Métropole, on Thursday last, Dr. W. Dougan, President, in the chair, supported by a large number of members and distinguished guests. The toast list was unusually comprehensive, but its length was compensated by the choice of orators, among whom we may mention Sir Walter Foster, who responded to the toast for the "Houses of Parliament;" Sir Hugh Gilzean Reid, who proposed that of the "Post Office Service;" Sir James Crichton Browne, to whom was entrusted the toast for the "Education and other State Departments," this toast being responded to by Sir George Kekewich; Professor Confield, who spoke on behalf of "Municipal Institutions; ' and Professor Sims Woodhead, who proposed, and Dr. Glover who acknowledged, the toast of the "General Medical Council." The toast of the "Medical Press" was proposed by Dr. J. Tatham, and was responded to by Mr. Wakley, jun., for the Lance, and by Dr. Gubb on behalf of the Mandey, Press and Carony, Mr. Webler resisted MEDICAL PRESS AND CIRCULAR. Mr. Wakley pointed out that the association was evidently one without grievances, inasmuch as the medical press had not so far been cognizant of its existence, an ideal position for an association of medical men. A very agreeable if protracted evening was spent, the intervals between the toasts being filled by appropriate musical selections rendered by musical volunteers.

THE MEDICAL PRESS.

The Midwives Bill.

This Bill has now been definitely dropped so far as the present session is concerned, but we have no doubt that more will be heard of the scheme on a future occasion. The aspirent midwife affects the pertinacity of the importunate widow.

THE Queen has intimated her intention to open the new wing of the National Hospital for Consumption at Ventnor during the stay of the Court at Osborne. The wing now in course of erection is named after the late Prince Henry of Battenberg, and the foundation-stone was laid last year by Princess Henry.

Royal College of Surgeons, Ireland.

FELLOWSHIP EXAMINATIONS.—The following gentlemen, having passed the necessary examination, have been admitted Fellows of the College:—Mr. A. A. Doyle, L.R.C.P.I., and L.R.C.S.I., and Mr J. P. Frengley, M.D., and B.Ch., Royal University.

Society of Apothecaries of London.

AT the June examination, the following candidates passed in :-

Surgery.—F. W. Chesnave (Section II.), S. E. Dunkin, H. H. J. Edwards (Sections I. and II.), W. M. Hocken, D. V. Lowndes (Section II.), V. S. Partridge (Section II.), D. O. Williams, W. P. Williamson.

Medicine.—S. J. H. Eastwick Field, H. H. J. Edwards (Section II.), T. H. Fox, J. B. Hall (Section I.), G. C. Hobbs (Section II.), A. Killick (Sections I. and II.), W. M. McLoughlin, A. Orme (Section II.), G. E. Seville, W. C. Stanham.

Furensic Medicine.—S. J. H. Eastwick Field, T. H. Fox, F. Golding. Bird, J. B. Hall, A. Kil.ick, W. M. McLoughlin, G. E. Seville, W. C. Sanham.

Midwifery.—J. R. Bentley, H. S. A. Davies, J. C. S. Dunn, S. J. H. Eastwick Field, T. H. Fox, L. Lehmann, F. Marriott, G. G. Membery. A. Orme. G. E. Seville,

The diploma of the Society was granted to the following candidates, entitling them to practise medicine, surgery, and midwifery:—F. W. Chesnaye, S. E. Dunkin, H. H. J. Edwards, F. Golding-Bird, W. M. Hocken, G. C. Hobbs, A. Killick, D. V. Lowndes, W. M. McLoughlin, W. P. Williamson, and D. O. Williams.

University of Glasgow.

AT the recent final examination for M.B., Ch.B., the following candidates attained distinction in the subjects indicated:—(S. Furgery and Clinical Surgery; P., Practice of Medicine and Clinical Medicine; M., Mid-

wifery.)

James Robert Chalmers (P., M.); John Craig 'P.); Hugh Camb
bell Ferguson (S., M.); George Gardner (M.; John Gardenr (S.,
P., M.; Jessie Downie Granger (P., M.); Jessie Sophia Beatrix
Hunter (M.); Hugh Miller (M.): Norman M'Leod Miller (M.);
Ebenezer Mitchell, M.A. (P., M.); James Hogg MacDonald (P.,
M.); Peter M'Fadyen M.); William Alexander Riddell (M.);
Arthur Robin (M.); Alfred George Stewart (P.); William Brown
Thomson (P.): Edythe Marjorie Stewart Walker (P.): Alexander
Laurie Watson, M.A. S., P., M.); Alexander Simpson Wells, M.A.
(S., P.)

The following have passed the Fourth (Final) Professional Examination:

For the M.B., C.M.—George Henry Beck Harvie, Alexander Page Robertson, Alexander Waugh.

For the M.B., Ch.B.—James Napier Baxter, Auguste Boyes, William Broad, andrew Brownlie, James Robert Chalmers, David Maclure Cowan, John Craig, George Morris Crawford, William Crerar, John Cullen, Charles Cheven Cumming, Sarah Davidson, John Lithgow Davie, James Austin Dickie, Hugh Campbell Ferguson, James Fuiton Find ay, G. Gardner, John Gardner, Hyam Goodman, M.A.; Jessie Downie Granger, James Garden Green, Andrew Kerr, Andrew Love, Ramsay Millar, Hugh Miller, Norman M'Leod Miller, Ebenezer Mitchell, M.A.; James Hogg MacDonald John M'Gilchrist, Norman Forbes MacLeod, Wil iam Johnston Maclure, John M'Millan, Ina Lochhead M'Neill, John Patton, Thomas Stephens Picken, John Reid (Lanark, William Alexander Riddell, Arthur Robin, Catherine Love Smith, David James Smith, William Stewart Stalker, Alfred George Stewart, Frederic Richardson Stewart, M.A.; Charles Pinkerton Thomson, William Brown Thomson, Henry Nisbet Turner, Edythe Marjorie Stewart Walker, Alexander Laurie Watson, M.A.; Alexander Simpson Wells, M.A.; Sara Whiteford, Robert Orr Whyte, M.A.; William Wright, John Doctor Young.

Aotices to Correspondents, Short Tetters, &c.

CORRESPONDENTS requiring a reply in this column are particularly requested to make use of a distinctive signature or nitials, and avoid the practice of signing themselves "Reader, "Subscriber," "Old Subscriber," &c. Much confusion will be spared by attention to this rule.

READING CASES.-Cloth board cases, gilt lettered, containing twenty-six strings for holding the numbers of THE MEDICAL PRESS AND CIRCULAR, may now be had at either office of this journal, price 2s. 6d. These cases will be found very useful to keep each weekly number intact, clean, and flat after it has passed through the post.

REPRINTS. - Authors of papers requiring reprints in pamphlet form after they have appeared in these columns can have them, at half the usual cost, on application to the printers before the type is

BACTERIOLOGY IN EXCELSIS.

A woman here dearly loves big words, and she does not always use them correctly. The other day a neighbour complained of incessant pain in her back, whereupon the user of big words said: "I would consult Dr. Pellets for pains in the back. He's the finest bacteriologist that I know of."—Pittsburg Chronicle.

Mr. Horn.-We will look into the matter and inform you of result in due course.

A CANDIDATE FOR THE HIGHER EXAM, will find all he requires in Stewart's "Manual of Physiology."

THE MEDICAL SICKNESS SOCIETY.

DR. BARRY, Ballyduff, co. Waterford, will be glad to hear the views of the Irish members of the Medical Sickness Society, London, as to the desirability of holding a meeting of medical men in reference to the working of above Society in so far as it concerns Ireland, and to arrange for a meeting to be held in Dublin or elsewhere at an early date. The meeting is being organised by Mr. B. A. Williams, of Queen's Square, Fermoy, a member of the Society.

J. H. S.—The Imperial Accident Insurance Company (17 Pall all, London) issues, we believe, a special policy for the insurance J. H. S. of doctors' carriages.

Dr. W. R. DERMOTT'S "Monistic Physiology" is marked for early insertion.

THE SYMBOL OF FAITH.

The ideal symbol of faith, observes an American exchange, is not the traditional maiden clinging to the Rock of Ages, but the bald-headed man confidently consulting the bald-headed specialist, and looking forward with enthusiasm to a great growth.

Mr. H. F. C.—Regret we must decline your communication; it is more suitable for a chemist's journal than for this.

Miss Gilbyrt.—We do not undertake to give medical advice. You had better consult your usual medical attendant who, no doubt, will have no difficulty in gratifying your curiosity as to the cause of your trouble.

"THOSE CURSES OF HUMAN LIFE."

"THOSE CURSES OF HUMAN LIFE."

WE are in receipt of a letter headed "Lucas Hospital, Wokingham," and signed "J. Stratton," which contains the following passage:—"We have no sympathy with papers which support the cowardly pests and curses of human life the vivisectors, who, if they had their deserts, would be hung up on the nearest trees." We are unable to find the institution referred to in the "Medical Directory," and the same remark applies to the signatory of the letter, a fact which may explain the writer's hysterical eloquence on a subject on which, probably, he knows little and feels strongly. Where the reason is weak the prejudice is strong!

Ex-STUDENT—We cannot hold out any hope that the General

EX-STUDENT.—We cannot hold out any hope that the General Medical Council will provide facilities for the qualification of impecunious or backward students, past or present. If, for pecuniary reasons, the medical career is closed to you, you had better seek some other sphere of activity. We are not cognisant of any fund on which you could draw to defray the expenses of a medical education, though, of course, there are plenty of scholarships open to the exceptionally gifted.

Vacancies.

Berrywood Asylum, Northampton.—Assistant Medical Officer for five years, unmarried. Salary £150, increasing to £200, with board, lodging, washing, and attendence.

ADAPTED TO THE NEW BRITISH PHARMACOPCEIA, 1886. Medium 800, price 21s., or in 2 Vols., 22s. 6d.

A Text Book of Pharmacology, Therapeutics, and Materia Medica. By T. LAUDER BRUNTON, M.D., D.Sc., F.R.S.,

Fellow of the Royal College of Physicians; Assistant Physician and Lecturer on Materia Medica at St. Bartholomew's Hospital; Examiner in Materia Medica in the University of London, in the Victoria University, and in the Royal College of Physicians, London; late Examiner in the University of Edinburgh.

ADAPTED TO THE UNITED STATES PHARMACOPIEIA BY F. H. WILLIAMS, M.D., BOSTON, MASS.

"It is simply a mine of wealth both for students and practitioners. It is thoroughly practical and thoroughly reliable. . is undoubtedly the best treatise on the subject in the English language."—British Medical Journal.

Medical Journal.

"A work which marks a distinct epoch, a turning-point in the history of medicine. It is not a mere compilation... but is essentially a new departure, breaking away from well-worn tracts into a new and almost unknown region."—Medical Times and Gazette.

BY THE SAME AUTHOR.

Disorders of Digestion: Their Consequences and Treatment.

This work contains, in addition to the Lettsomian Lectures, a number of other Papers by the Author on similar subjects. 800, 10s. 6d.

"Distinguished by accurate observation and original thinking, these papers have been largely instrumental in moulding current medium opinion in regard to many of the subjects with which they are concerned. —*Edinburgh Medical Journal*.

"We can cordially recommend the volume as one which combines such practical and technical information and sound common sense.—

PEPSINA P

DOSE-2 to 4 GRAINS.

ACID GLYCERINE

DOSE-I to 2 DRMS.

In this preparation advantage has been taken of the solubility of Pepaine in Glycerine to produce a convenient and desirable liquid form of this valuable medicine; whilst the preservative qualities of the menstruum confer upon the Acid Glycerine of Pepsine the property of keeping for any length of time.

May be prescribed with most substaces compatible with Acids. In 4 oz., 8 oz., and 16 oz. Bottles, and in Bulk.

The published experiments of G. F. DOWDESWELL, Esq., M.A. Cantab., F.C.S., F.L.S., &c., Dr. PAVE, Professor Tuson, the late Professor Garron, Dr. Arnold Lees, and others, conclusively demonstrate the excellence, high digestive power, and medicinal value of the above preparations.

"Easily digestible. . . decidedly superior to a clear extract."-LANCET.

LEUBE-ROSENTHAL'S IMPROVED

MEAT

Presents in the most readily assimilable form all the best properties of the meat, unaltered by heat, and constitutes a strong, safe, and palatable diet of special nutritive value for the sick or convalescent. Being non-irritant and of relishing flavour, is acceptable to, and retained by, the weakest stomach, and is particularly rich in peptones. Is not an "extract," but the meat itself; and does not constipate, but aids and improves digestion.

Approved by scientific Experts both at home and abroad, and Recommended by Physicians. Analysis on application.

Price 2/- per Tin of all Chemists.

Always Trustworthy.

T has been proven by clinical tests that Bromidia is the best and safest hypnotic yet known to the profession.

It is always of the same strength, and hence can always be relied upon, to produce the same results under the same conditions.

It is so well known and so well liked by the profession everywhere, that it can be obtained in almost every drug store in every country in the world.

Avoid substitution. The doctor should always take special care to get the genuine, which is only made by BATTLE & CO.

DOSE: -One-half to one fluid drachm, repeated as indicated.

A Sample Bottle of BROMIDIA and Pamphlet will be forwarded free of charge to Medical Men on application to

ROBERTS & CO., 76 New Bond St., London,

GENERAL DEPÔT FOR GREAT BRITAIN.

BATTLE & CO., St. Louis, Mo., U.S.A.

'SAXIN'

Has been aptly termed the "Sweetest thing on earth." It is about 600 times sweeter than sugar and more delicate in flavour. 'Saxin' undergoes no change in the system, and may be safely prescribed in all cases where sugar is harmful.

Saxin.' 1/4 gr., is supplied in bottles of 100 and 200, at 7d. and 1s. 1d. per bottle.

'EMOL-KELEET'

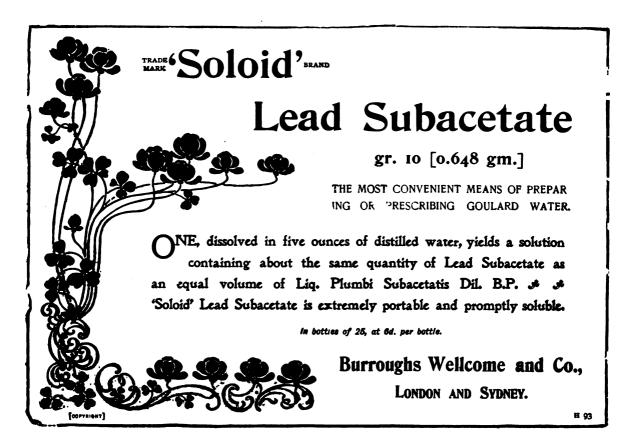

Is a natural powder, containing a large proportion of native silicates. It has proved successful for drying weeping surfaces when all other powders have failed. Its soft, silky texture, soothing influence and other physical qualities enhance its healing action.

Emol-Keleet' is supplied in neat metal boxes, at Od. per box.

BURROUGHS WELLCOME AND CO., LONDON AND SYDNEY.

M 10

BAYER'S

PHARMACEUTICAL SPECIALITIES.

An ideal astringent in infantile diarrheea, colic enteritis, dysentery, etc. An acetic derivative of tannin without taste or smell. Insoluble in water or dilute acids, but easily soluble in the presence of alkalis.

TANNIGEN

(Triacetyl of Tannin).

An ideal substitute for the Salicylates, having no irritating effect on the stomach, through which it passes unchanged, decomposing only in the alkaline intestinal fluid. It is free from the unpleasant after effects so frequently attending the use of Salicylic Acid and its salts.

An excellent substitute for Codeine. In doses of 1-12th of a grain. Heroin has given most excellent results in cases of Bronchitis, Pharyngitis, Catarrh of the Lungs, and in Asthma Bronchiale. In the latter two cases the dose may be increased to 1-6th of a grain.

ASPIRIN

(Acetic Ether of Salicylic Acid.)

HEROIN

(Di-acetic Ether of Morphine).

MAY be prescribed in all cases where it is desired to produce an astringent action on the intestinal mucus. Renders especially valuable service in acute and chronic colic, and is a specific in summer diarrheea of children.

Dose: Children 2 to 5 grains; Adults, 8 to 12 grains 4 or 6 times a day.

It has an agreeable, slightly acid taste, favourably contrasting with the repugnant sweet taste of the Salicylates. Extensive clinical trials have proved the value of Aspirin as a perfect substitute for Salicylic Acid and its salts.

Dose: 16 grains, 3 or 4 times a day.

HEROIN does not cause constipation, and may be administered to patients with a weak heart who cannot tolerate Morphine.

Hydrochloride of Heroin. A neutral Heroin salt, easily soluble in water, and suitable for subcutaneous injection.

Dose, subcutaneously, 1-20th to 1-6th of a grain.

Trional, Tannigen, Salophen, Lycetol, Creosotal, Duotal, Heroin, Aristol, Tetronal, Analgen, Losophan, Somatose, Iron Somatose, Milk Somatose, Phenacetine-Bayer, Sulfonal-Bayer, Piperazine-Bayer, Salol-Bayer.

Samples and Literature may be had on application to the Wholesale Depot for all Bayer's Pharmaceutical Specialities.

THE BAYER CO., Ltd., 19 ST. DUNSTAN'S HILL, LONDON, E.C.

Also at MANCHESTER, GLASGOW, and BRADFORD.

LISTERINE.

THE STANDARD ANTISEPTIC.

- LISTERINE is a non-toxic, non-irritating and non-escharotic antiseptic, composed of ozoniferous essences, vegetable antiseptics and benzo-boracic acid.
- LISTERINE is sufficiently powerful to make and maintain surgical cleanliness in the antiseptic and prophylactic treatment and care of all parts of the human body.
- LISTERINE has ever proven a thoroughly trustworthy antiseptic dressing for operative or accidental wounds.
- LISTERINE is invaluable in obstetrics and gynecology as a general cleansing prophylactic, or antiseptic agent, and is an effective remedy in the treatment of catarrhal conditions of every locality.
- LISTERINE is useful in the treatment of the infectious maladies which are attended by inflammation of accessible surfaces—as diphtheria, scarlet fever and pertussis.
- LISTERINE diluted with water or glycerine speedily relieves certain fermentative forms of indigestion.
- LISTERINE is indispensable for the preservation of the teeth, and for maintaining the mucous membrane of the mouth in a healthy condition.
- LISTERINE employed in the sick-room by means of a spray, or saturated cloths hung about, is actively ozonifying and rapidly oxidizing in its effects upon organic matter afloat in the atmosphere.
- LISTERINE is of accurately determined and uniform antiseptic power, and of positive originality.
- LISTERINE is kept in stock by all worthy pharmacists everywhere.

DR. J. COLLIS BROWNE'S CHLORODYNE

THE ORIGINAL AND ONLY GENUINE.

From Symes & Co., Chemists, Medical Hall, Simla, January 5, 1880.

To J. T. DAVENPORT, Esq., 33 Great Russell Street, Bloomsbury, London.

Dear Sir,—Have the goodness to furnish us with your best quotations for Dr. J. Collis Browne's Chlorodyne as being large buyers, we would much prefer doing business with you direct than through the wholesale houses. We embrace this opportunity of congratulating you upon the widespread reputation this justly esteemed medicine has earned for itself, not only in Hindostan, but all over the East. As a remedy of general utility, we much question whether a better is imported into the country, and we shall be glad to hear of its finding a place in every Anglo-Indian home. The other brands, we are happy to say, are now relegated to the native bazaars, and judging from their sale, we fancy their sojourn there will be but evanescent. We could multiply instances ad infinitum of the extraordinary efficacy of Dr. Collis Browne's Chlorodyne in Diarrheea and Dysentery, Spasms, Cramps, Neuralgia, the Vomiting of Pregnancy, and as general sedative, that have occurred under our personal observation during many years. In Choleraic Diarrheea, and even in the more terrible forms of Cholera itself, we have witnessed its surprisingly controlling power. We have never used any other form of this medicine than Collis Browne's, from a firm conviction that it is decidedly the best, and also from a sense of duty we owe to the profession and the public, as we are of opinion that the substitution of any other than Collis Browne's is a deliberate breach of faith on the part of the chemist to prescriber and patient alike.

We are Sir, faithfully yours,

SYMES & CO.,

His Excellency the Viceroy's Chemists.

Sole Manufacturer, J. T. DAVENPORT.

BRITISH MEDICAL ASSOCIATION

Media held in Edinburgh this year, is guaranteed to be a perfectly pure Extract made from Malted Barley only. The grain used is chosen with the greatest possible care; and as The Distillers Co. Ltd., purchased over 400,000 quarters during last year, it must be apparent that their knowledge is exceptional. Malting is conducted entirely on their own premises, the machinery employed is of the most perfect description, and every lot made is carefully tested befores being bottled.

The "D.C.L" MALT EXTRACT can be obtained combined with Cod Liver Oil. Medical Men can have Samples sent free on application, and are respectfully urged to prescribe "D.C.L." to their patients. otherwise very inferior makes may be supplied.

There are several older makes of Malt Extract now before the public which are valueless in Dyspepsia, as they are utterly innocent of Diastase and are artificially thickened with Dextrine.

"D.C.L." MALT EXTRACT is reliable in every particular.

Sole Makers: THE DISTILLERS CO., Ltd., Edinburgh.

WHAT IS FRICTION?

It is one of the natural laws which prevents an old style ball-touch-ball bearings from revolving at a higher rate of speed than 18,000 revolutions a minute. It is also a natural law that admits of the new "Cleveland" ball and roller bearings revolving 35,000 revolutions a minute without heating. "Twice as Easy" well describes the running of the "Cleveland" Cycle fitted with these bearings.

KAISER FRIEDRICH (A Mineral Spring containing Soda and Lithia.)

OFFENBACH A/M MAIN.

Observations made in the Hospital of the University of Göttingen have proved that when the water of the Kaiser Friedrich Quelle is taken the urine becomes more capable of retaining uric acid in solution. The use of the water to the extent required to bring about this result may be continued for a long time without producing any ill effects. It is therefore an excellent table beverage for all those who either have a tendency to the uric acid diathesis or suffer from its consequences, such as sandy deposit in the urine, gout, and formation of concretions. Special terms to Medical Men. Samples supplied gratis by all Wholesale Dealers in Mineral Waters, or forwarded direct from the Spring at Offenbach a/m Main,

"The predominance of Magnesium Sulphate and the presence of Lithium in APENTA WATER having been recently pointed out by Professor Pouchet, I determined to ascertain for myself the properties of this water, and for this purpose I prescribed it to a large number of my patients.

"is an excellent, very active purgative, and of strictly constant composition. Its action is mild and reliable, and a wineglassful or half a glass acts as an aperient without producing either griping or discomfort. It is the Water specially suited for the treatment of habitual constipation. Moreover, by its special and constant composition this Water appears to me to merit a place by itself in the therapeutics of Mineral Waters."

Paris, 4th February, 1899

Dr. E. LANCEREAUX,

Professeur à la Faculté de Médecine, Paris; Médecin honoraire des Hôpitaux; Membre de l'Académie de Médecine.
